The ships are loaded at the expence of the Hong merchants, and generally complete their cargo at Wampoo, unless they draw so much water as to require to be carried farther down the river, before receiving the whole of their burden. When the loading is completed, the captain sends intimation to the Hong merchant, who then applies to the Ho-poo for the license to sail and to procure a pilot; and this license ought to be preserved till the vessel has passed Macao, both as a proof that all the duties have been paid, and as a claim upon the Chinese for assistance in case of accidents. After the departure of the ships for Europe, the supercargoes of the companies at Canton begin to bargain with the Hong merchants for the next cargo; and, by acquiring on the spot a knowledge of the situation of these merchants, and of other circumstances, they have thus greatly the advantage of private traders, in making profitable contracts.

Expences of trade.

The following table of expences, attending a commercial voyage to Canton, according to the statements of M. De Guignes, * may be acceptable to mercantile readers:—

	Dollars.
Duty upon a ship 50 Chinese feet in length, and 20 in breadth = 1000 feet, or 100 Tchang . .	665
Present to the Ho-poo, about	2708
Two per cent. upon the two payments for the secretaries of the Ho-poo	67
Expence of pilot to Wampoo	40
Additional gratification	4
Hire of a lodging at Canton	600
Licence for each country boat employed in unloading the cargo	15
Hire of the boat, &c.	9
Salary to interpreter, and expence of licence to sail	184
To the mandarins at Wampoo	200
To the comprador, or purchaser of provisions .	200
To the soldiers	4
To the mandarins upon leaving Canton	6
To the pilot, for going down to Macao	60
To the boats, which assist in passing the bars . .	4
Total about L. 1150, or	4766

The fare of the country boats from Canton to Wampoo, is generally from four to six dollars; but it is recommended, upon finally quitting Canton, to use the ship's boat, instead of the Chinese craft, which would expose the trader to demands for money at every custom-house. †

MANUFACTURES AND TRADES.

Porcelain.

Few of the manufacturing arts have attained any high degree of excellence in China; and almost the only one, in which they excel, is in the art of pottery. Even the superior quality, however, of their porcelain, is more owing to the excellence of the materials which they possess, and the care with which they select and purify them, than to any ingenuity or skill displayed in the process. Their taste in shaping and ornamenting their porcelain vessels is generally acknowledged to be most wretched; and they can neither finish nor paint their ware in a manner equal to that of European manufacture.

Materials.

The two principal substances, which enter into the composition of their porcelain, and upon the due preparation and proportioning of which its quality depends, are called Kao-lin and Pe-tun-tse: the former, is a fine soft clay, or soap-stone, mixed with a few grains of mica; and the latter a kind of granite composed chiefly of quartz, with a small quantity of mica; the whitest of each, and that which has a greenish hue, is always preferred, and carefully purified. The Pe-tun-tse, after being broken by an iron club, is pounded in mortars by means of levers, headed with stone and bound with iron, which are sometimes worked by water like the hammers of paper mills. The powder is then thrown into a large vessel full of water, stirred with an iron shovel, and left to settle. A kind of cream, about four inches thick, then rises to the top, which is repeatedly scummed off as it collects, and poured into another vessel filled with water. The dregs, which remain behind, are then pounded anew, and submitted to the same process. The cream, thus collected, is allowed to remain in a vessel of water, till it form a crust at the bottom, and the water above become perfectly clean, which is then gently poured off, and the paste thrown into large moulds to be dried; but, before becoming entirely hard, it is cut into small square cakes like bricks, which are sold by the hundred.

The kao-lin is found in large mines, under a stratum of red earth; and, though almost sufficiently prepared in its natural state, is made to pass through the same process, and formed into bricks like the Pe-tun-tse.

These two substances are then mixed together, the kao-lin acting as a cement to unite the particles of the Pe-tun-tse. For the fine porcelain, equal parts of each are employed; for that of a secondary quality, four parts of the kao-lin are added to six of the Pe-tun-tse; and for that of the lowest kind, one part of kao-lin to three of Pe-tun-tse. Instead of kao-lin, the manufacturers sometimes employ a kind of greasy chalk-stone, named Hao-tche, which is pounded, purified, and formed into cakes, in the same manner as the other substances. The porcelain, made of this material, is finer, whiter, and lighter, but, at the same time, more brittle and expensive, than what is made with kao-lin; and, hence, the workmen generally content themselves with dipping the formed paste into a thick tincture of Hao-tche, for the purpose of giving it a greater degree of whiteness. Another kind of substance of the nature of gypsum, called She-kao, is also occasionally used, but it wants the solidity of the kao-lin.

Mode of working.

When the substances are mixed in the desired proportions, the mass is thrown into a large pit, well paved and cemented; and is then kneaded chiefly by treading, till it become hard. From this mass the workmen take their portions, which they spread out upon large slates, and knead and roll the substance in every direction, destroying every vacuum, and removing every extraneous matter, even the smallest hair or grain of sand. Vessels with plain surfaces, are then formed, generally with the wheel; and, when a cup has thus received its proper height and diameter, it passes to another wokman, who forms its base; then to a third, who gives its proper shape by a mould; then to a fourth, who polishes its edges, and diminishes its thickness; and so on, through a variety of hands, perhaps to the number of 20, before it is ready for the furnace. In the larger and more complicated pieces, in which there are spouts, handles, rings, &c. and in figures of trees, animals, busts, and other ima-

---

By this author, the dollar is estimated at nearly 4s. 10*d.* sterling.

† For a variety of other useful and particular directions respecting the navigation from Macao to Wampoo, we must refer to *Voyage a Peking* par M. De Guignes, tome iii. p. 277.

Manufactures.

ges, which are fashioned upon moulds, or modelled by the hand, the different parts are prepared separately; and, when nearly dry, are cemented together with paste, of the same nature as the substance, of which they are composed; while the seams, being polished with a knife and covered with varnish, are completely concealed. When a piece of porcelain is thus properly fashioned, it passes into the hands of the painters, one of whom traces out the circle to be coloured around the brim, another designs the flowers, a third the mountains or rivers, a fourth the animals, a fifth the human figures, and a sixth applies the paint. When the porcelain has received its form, colours, and ornaments, it is then conveyed to the furnace; and each piece is put into a separate case or box, the bottom of which is covered with a layer of fine sand, over which again is thrown powder of kao lin. The case is covered by the bottom of another case, which enters it only so far as to shut it entirely, without touching the porcelain below; and these piles of cases are then placed in the furnace, upon a bed of coarse sand, the finer kinds being in the middle, the coarser at the farther extremity, and those, which have most body and strongest colours, at the mouth. These piles are placed closely together, and made to support each other by pieces of earth at the top, bottom, and middle; but still so as to allow the flame to find a free passage on every side. It seldom happens that a baking succeeds entirely; and from too strong a heat, or insufficient cases the whole is sometimes completely spoiled, and the porcelain and cases found converted into a shapeless mass, as hard as flint. Hence smaller furnaces are more frequently used; and the cases are introduced into the furnace, and taken out when supposed to be sufficiently baked, by means of a long wooden handle, with an iron plate at one extremity.

Different kinds of porcelain

The Chinese name for porcelain is Tse-kee; and the best is made in the village of King-te-ching, in the province of Kiang-see. The finest is reserved for the emperor; and it has been questioned, whether any of the largest and most beautiful pieces have ever been brought to Europe. The porcelain pieces are painted of various colours; but the most prevailing is white, with blue flowers; and the greater part of what is transported to Europe is of this colour. An inferior kind, entirely white, is also brought to Canton, in order to be painted there, according to the orders of the European merchants. It is said, that one of the most esteemed and expensive kinds is of a red colour, which is sometimes uniform throughout, and sometimes merely sprinkled in the form of small spots; which is done by dipping the end of a pipe covered with gauze into the colouring matter, and then blowing it upon the porcelain. There is also a black or lead coloured porcelain, sometimes interspersed with gilding, which is in great request; and this gold colour is prepared by rubbing with the palm of the hand, in a plate of porcelain, gold dust mixed with water and sugar. It is then applied with a pencil dipped in clear gum-water; and, when the vessel has passed through the furnace, the gold is polished with a fine wet sand.

Earthen ware.

Besides porcelain, they form very beautiful vases of a brownish coloured clay, some of which are from three to five feet deep, and four or five in diameter; the finer kinds of which are used for holding gold fishes, flowers, aquatic plants, &c. and the coarser are employed for keeping seeds, fruits and water. In this manufacture, particular attention is paid to the wants of the people, and they are supplied, at a cheap rate, with spoons, cups, lamps, and various kitchen utensils, of this baked earth. There are vases also of fuller's earth, which are used for cooling and sweetening water; and a coarser kind of earthen ware, which is supposed to communicate a more delicate taste to rice, when boiled in it, and is therefore much used in culinary purposes.

Manufactures.

Glass.

It has been considered as a remarkable instance of the want of ingenuity in the Chinese, that they should have been so long in possession of the art of making porcelain, so analogous to that of glass, without having discovered the mode of producing this useful manufacture; and it is said, that they even profess to hold it in very little estimation. At the recommendation of the Jesuits, a French family, made an attempt, in the last century, to introduce this manufacture at Pekin, but failed of success. In Canton, they have learned to melt old glass, and cast it in a new form; but their common mirrors are still generally made of a polished metal, which is supposed to be a compound of zinc and copper. A glass-house is said, indeed, to be kept up at Pekin, where a few vases and other articles are made; but is regarded merely as an establishment of pomp, and as an appendage to the splendour of the court.

Cloth manufacturers.

Their cloth manufactures do not appear to have undergone any recent or progressive improvement; but, from their close adherence to ancient practices, they have long remained entirely stationary.

Silk.

The use of silk has unquestionably been known in China from a very remote period; and mention is made of a kind of brocade in the annals of Tcheoo, about 780 years before Christ. There are strong grounds, however, for the belief, that the culture of the silk worm was first introduced into the Chinese empire by a colony of Jews, after the expedition of Alexander to India had opened a communication with these countries; and is at least certain, that they are the best manufacturers of that article in China, and abound chiefly in the silk provinces. But, in whatever way, and at whatever period, the manufacture of silk was introduced, it has been cultivated to such an amazing extent, that, besides the immense quantities annually exported, it forms the principal clothing of the greater part of the inhabitants. The best is produced in the province of Tche-kiang, and is distinguished by its superior fineness of texture, softness to the touch, and whiteness of colour. The greater quantity of silk stuffs are manufactured in the province of Kiang-nan, and its capital Nankeen, from which is procured all that is intended for the use of the emperor. The Chinese manufacture this substance into a great variety of stuffs, plain, striped, flowered, napped, clouded; gauzes, velvets, and brocades of every different colour, especially violet, red, yellow, and black; and a multitude of other kinds, whose names even are unknown in other countries. They make several kinds similar to those of Europe, but very inferior in point of workmanship. Neither are the silk buttons, ribbons, and stockings, which they manufacture in Canton after foreign patterns, equal to those of France and England. Their velvets are bad; their Nankeen and Pekin satins are very unequal, and liable to cut. Their gold brocades, though extremely brilliant, when fresh from the hand of the workman, are easily tarnished by air and moisture, as the gold, which they employ, is only a kind of gilt paper. They excel chiefly in the manufacture of gauzes, both plain and flowered, of great variety and beauty. There are two kinds, which are more generally used in the country than any other. The first, called Too-an tse, is a kind of satin, much stronger, but with less lustre, than what is manufactured in Europe. The other, a sort of greyish coloured taffety, is very closely woven, and yet extreme-

Manufactures.

ly pliable, is not apt to cut, and washes, like cotton cloth, without losing much of its lustre: it is chiefly used for linings, drawers, and other under parts of clothing. There is another kind, called Kien-tcheoo, which is manufactured from the silk of an insect, somewhat different from the common silk-worm, and which abounds particularly in the province of Shang-tong. This stuff is very inferior in point of lustre, rough grained, and at first sight resembling the woollen cloth called drugget; but washes well, lasts long, is not easily spotted by grease, and is greatly esteemed by the Chinese. The greater part of the wrought silk stuffs exported to Europe, is manufactured at Canton, or in its vicinity, with the silk of that province, which is rather of an inferior quality. The exported raw silks are from the province of Kiang-nan. And it has been recommended to those who purchase either kind, to inspect the bales and boxes with care; and particularly to examine them internally, as they are often made up within of very inferior sorts.

Nankeen.

The stuff, so well known by the name of Nankeen, is made of cotton from the province of Kiang-nan, which naturally possesses the peculiar yellow hue, which distinguishes the cloth in question; but it is said to lose this colour, when cultivated in the more southern provinces, though it has been raised in great perfection, both as to the size and colour of the pods, at the Cape of Good Hope.

Linen.

The Chinese linen cloths are generally narrow and firmly wrought. One of the best sorts is from Nankeen; and another kind from the province of Fo-kien, called by the Chinese Ko-poo, and by the Portuguese Noonés, is very light, clear, and glossy.

Paper.

In the more early ages, the Chinese wrote with an iron style upon tablets of bamboo, or plates of metal; afterwards also upon cloth and silk stuffs; and at length, in the reign of Ho-tee, about 150 years before Christ, a mandarin named Tsay-lun produced the first paper from the bark of trees and old linen. In this manufacture they have greatly improved, and produce it in immense quantities. They employ, in making different kinds of paper, hemp, nettles, and similar plants, the bark of the mulberry, and of a tree called Koo-tchoo, the straw of rice and other grain, the cods of the silk-worm, and the cotton shrub, rags, and old paper, and especially the bark and fibres of the bamboo. That which is made from cotton rags is the best, remarkably white, soft, and durable; but that from the bark of the Koo-tchoo is most commonly used, and hence paper is generally called by that name in China. In making it from bamboo, the second bark, which is soft and white, is chiefly used, is macerated in water, boiled in kettles, reduced to a paste by pounding in mortars, moulded in frames made of fine threads of bamboo, and often formed into sheets from three to ten feet in length, one of which is sometimes sufficient to cover the whole side of a room. The finer kinds of writing-paper are dipped in a solution of two ounces of alum, and six ounces of well purified isinglass, in twelve pints of water; an operation, which renders them very smooth, soft, and white, and also prevents the ink from sinking; but, at the same time, makes them more apt to cut, to be injured by moisture, and attacked by worms. A particularly strong and beautiful kind of paper is used at Pekin in the windows, instead of glass, which is of a rose colour, and so thick as to be easily split into two or three laminæ. It is said to be brought from Corea, and to be partly composed of the tow of silk.

Ink.

The Chinese are said to have received their improved methods of preparing ink from the Coreans, and to have possessed the art in perfection only since the 9th century. The Chinese ink is made from blacking, produced by the smoke of different substances; but principally that of pines, and of oil in lamps, mixed with strong isinglass, and a little musk to correct the odour of the oil. These ingredients are formed together into the consistency of paste, divided into cakes, and put into moulds. The best is made of the lightest soot, produced by oil in lamps, with isinglass of ass's skin; and the principal manufacture of this superior kind is in the district of Hoei-tcheoo-foo, a city in the province of Kiang-nan, where the workmen are supposed to possess some secrets in the process, which they conceal even from the rest of their countrymen. They have apartments, divided into a multitude of small cells, in which lamps or pieces of pine wood are kept continually burning, to produce the proper blacking; and different kinds of oil are burnt in the different apartments, each of which yields a particular sort of ink. The Chinese are said to possess the art of washing this ink from written paper, and of then separating the ink from the water, so as to be again fit for use, while the paper also is beaten, boiled, and formed into new sheets. Good China ink, should have a smooth and shining fracture, when the stick is broken; should shew a good black colour, when pounded and mixed with water; should dissolve easily, and flow freely beyond the pencil. The cakes should be preserved from moisture; and, if accidentally wet, ought not to be exposed to the sun, which makes them break into chaps or cracks.

Trades.

Hair pencils.

The Chinese use in writing, pencils or brushes of different sizes, made of the hair of various animals, but chiefly that of the rabbit. In writing, they hold the pencil perpendicular between the thumb and the two first fingers, so that the point is fully an inch beyond the little finger, while the hand rests upon the wrist. They write from top to bottom, in the form of columns, beginning on the right of the page; so that, upon commencing a new line, the hand covers those which were last written; a circumstance, which would often occasion great inconvenience, if their ink had not the quality of drying quickly.

Mode of writing.

Printing.

The art of printing was invented in China, about 950 years after the birth of Christ; but it is more like the engraving on copper-plates, than the moveable types of an European press. The characters are first written out by a fair and skilful writer, on sheets of thin transparent paper. These are then glued upon boards of hard wood, generally of the apple or pear-tree, when the engraver, following the traces of the writing, carves the characters upon the plank, afterwards hollowing out the intermediate parts of the wood. Each of these boards generally contains two pages, which are printed on one side only of a sheet of paper, of the same size as the engraved plank, generally royal octavo, and afterwards folded together. The printer places the board in a level position, lays on the ink, which is more fluid than that which is used in writing, with a hard brush; applies the sheet of paper; presses it down with another softer kind of brush, with greater or less force, according to the quantity of ink on the plank; and thus throws off four or five sheets, without having occasion to renew the ink. In this way they can throw off copies, as in stereotype printing, according to the demand; but, as all their works must be executed in the same style, it becomes a very inconvenient matter to preserve the engraved planks, as one chamber is scarcely sufficient to contain those which compose one work, and as they are apt to be injured by the worms. They have also a few moveable types of those characters, which occur most frequently, and which they employ in printing the Gazette, and other smaller publications. In cases of great urgency, such as an edict of government, which may require to be printed in the course of a day or night, the characters are traced and engraved on a block or board, covered with yellow wax, from which the impressions are then taken in the usual way. A Chinese author, must print at his own expence, unless he be a mandarin, in which case he presents his work to the emperor, and, if approved by the imperial college, it is printed at the expence of government. There are numerous printing-offices in China, especially in the city of Soo-tcheoo-foo, in the province of Kiang-nan, where a considerable trade is carried on in books, which are chiefly however collections of poetical pieces.

Seals and wax.

It is the custom in China to give no writing to the public, without the seal of its author. These seals are almost always of a square form, and a few of an oval shape. They are commonly made of a kind of pot-stone, which abounds in the country; but the more wealthy use seals of agate, coral, jasper, and rock crystal. The characters upon these seals are for the most part in the antique form of writing, which is of a square and angular figure; though there are some in the common hand, which are affixed to familiar epistles. The inscription on their seals is either some favourite sentence, or the name of the person to whom they belong; and the impression is made upon a red coloured substance mixed with oil, kept carefully covered in a small porcelain vase, to preserve it from drying, and in a proper state for use.

Engravers.

The frequency of seals gives employment to a number of engravers, many of whom are said to be remarkably expert and ingenious in their profession. They are unrivalled, especially in the art of cutting ivory; and with the simple instrumentality of the hand, they execute in the neatest style, and at a cheaper rate than in any other part of the world, the finest fans, sticks of fans, models of temples and other buildings, and all kinds of toys and trinkets. Out of a solid ball of ivory, with a hole in its centre, about half an inch in diameter, they have been known to cut fifteen distinct hollow globes, one within another, completely detached from each other, capable of being turned round in any direction, and each of them, at the same time, carved full of open work like the sticks of fans. These curious specimens of such nice workmanship, are done by common artists, and in so expeditious a manner, that they may be purchased for a very small sum.

Artists.

The Chinese artists in short are represented as capable of attaining the high degree of excellence in every thing, that requires neatness and delicacy of execution, and might soon excel those of most other countries, if the pride of their government did not discourage the introduction of new inventions and foreign arts. Nothing, it is said, can exceed the ingenuity with which they fabricate the most beautiful toys and finest pieces of mechanism. Mr Barrow relates, as a proof of this remark, that a Chinese at Canton, who had never before seen an European watch, succeeded in making one in every respect similar, except the main spring; and he adds, that, in the short space of half an hour, two Chinese artists took down and put up again, piece by piece, the most complicated glass lustres, consisting of several hundred pieces, which had been sent as presents from England to the emperor; an operation, which was considered as so difficult, that it was thought necessary for the artists who accompanied the embassy, to see it several times performed, in order that they might be able to combine the articles properly, when arrived in China.

Machinery.

The Chinese make very little use of machinery in their manufactures and arts; and the few machines, which they do possess, are of the most rude and simple construction. It is conjectured, that the invention and application of works of machinery is purposely discouraged by the government of that country, lest they should diminish the gains and subsistence of a population already sufficiently in want of employment.

A sufficiently striking proof of the general low state of the most common arts in China, is to be found in the universal practice of the different artisans performing their work, not in their respective shops, but in the houses of their employers; and in the limited number, as well as inferior efficiency of the tools with which they operate. This is not only the case with the menders of iron utensils and of broken glass or porcelain, like the tinkers in Europe, but with almost every kind of handicraft in the empire.

Barbers.

The most numerous pliers in the streets, besides the porters, are the barbers, who are provided with all the necessary apparatus, of a seat, warm water, soap box, brushes, and a variety of instruments, unknown to the same profession in Europe; and they proceed to perform their various services, in the open streets, wherever a customer applies; shaving off every hair on the face, except the eye brows and eye lashes; plucking the hairs from the nostrils, cleansing the ears, adjusting the eye brows, dressing the hair, pairing the nails, and all this for so mere a trifle, that the very lowest of the people are enabled to employ them.

Joiners.

The joiners use few tools, and work clumsily. Their axes are small, and serve also as hammers. Their pincers consist of an iron rod, about a foot in length, and an inch in breadth, one end of which is broader and thinner than the other, and perforated in two or three places; and on the other end, is a quadrangular foot, about an inch square, and sharp at the corners, with a loose quadrangular ring exactly fitted to the foot, by means of which a nail is easily extracted, upon the principle of the lever. Instead of using a bench they sit upon the ground, placing the board of wood against their belly, and holding it with their feet.

Tailors.

Their tailors use very small scissars, and needles with round eyes; and instead of a smoothing iron, they have a little pan of brass or copper without feet, into which they put some burning charcoal, and with which they smooth their seams.

Workers in varnish.

The artists, who make varnished or japanned articles, are very numerous; but those at Canton, whether from the inferior quality of the varnish, or the haste in which they are frequently obliged to work, do not produce such excellent work, as those in the province of Kiang-nan. None of the Chinese artists, however, equal in this department those of Japan, whose productions are greatly valued, and purchased at a high rate in China. Those, who work in varnish at Canton, have their shops in the more retired quarters of the town, and commonly keep their windows shut, as if with a view to conceal the secrets of their art. The articles, varnished, are chiefly made of pasteboard or thin wood; and are almost universally stained of a black shining hue. When the varnish is put on, the articles are carefully preserved from dust, and dried slowly in the shade.

Though the Chinese mechanics are remarkably industrious, frugal, and capable of living upon very little; yet many of them are unable to find sufficient employment and subsistence for themselves and their families. They are often, therefore, engaged in begging as well as in working; but the alms, which they receive, is miserably small, being frequently nothing more than as much rice, as will cover the finger nail. There are, however, mutual associations among those, who follow the same trade, resembling the friendly societies in Great Britain, by means of which, funds are provided for the relief of those who fall into sickness and indigent circumstances.

Fishers.

Among the numerous employments of the Chinese, that of the fishers requires to be particularly noticed; both on account of the multitudes, who are engaged in that profession, and on account of the various modes, in which they practise their art. They use worms and crabs as baits to catch eels and small fish; or drag with great nets, fastened to bamboo poles; or sail up and down with a swimming net, fastened between two boats; or place in the shallows large bamboo and willow baskets, or nets of strong twine attached to stakes. But the most remarkable of their methods are the two following: They have long narrow boats, on one side of which is a large plank painted white, turning upon hinges; and on the other side a net extended the whole length of the boat. When these planks are let down on a level with the water in moon-light nights, or with a fire lighted in the boat, the fish, especially a kind of mullet, deceived by the light and whiteness of the board, leap from the water into the boat. In the other method, they employ a species of corvorant, supposed to be the *pelicanus aquilus*, or *man of war*, which they take out upon the lakes and rivers in boats or rafts. On the neck of the bird is a small iron ring, which prevents it from swallowing the fish, and to this ring is fastened a light cord for pulling it toward the boat. As soon as a fish is seen near the surface of the water, the bird dives towards the spot, and generally brings it up in his bill, from which it is taken by the fisherman; and after labouring a certain time for his master in this way, the ring is taken from his neck, and he is allowed to fish for himself. Though the fishers are permitted to follow their trade without being subject to any exaction or duty, yet they are the poorest and most miserable looking part of the community, perhaps owing in some measure to the bad effects of their fish diet, which, however, they endeavour to correct by the use of onions, garlic, and the flesh of ducks. They raise these vegetables on the waters, on large rafts of bamboo covered with earth, and towed along with their boats; while the ducks are so trained as to leave the boats in quest of food, and return thither, at the signal of a whistle.

CHARACTER AND MANNERS.

Exaggerated estimate of their attainments.

Respecting the general attainments of the Chinese in the most important arts and virtues of civilized life, the most extravagant and contradictory sentiments have been advanced by contending authors. By some, they have been extolled as the oldest, wisest, most learned, most ingenious, and most virtuous of nations, superior to all the other inhabitants of Asia, and capable of standing a comparison with the most enlightened people of Europe. Others again have, in equally unqualified terms, derided all their pretensions to antiquity, science or virtue, condemned their government as utterly abominable, and reprobated their manners as absolutely barbarous. The exalted representation of the empire and inhabitants of China, communicated to Europeans by the writings of the early Jesuit missionaries, are universally acknowledged to have been too highly coloured *in toto*, and to have been altogether unfounded in various instances. These erroneous views no doubt proceeded partly from partial feelings in the minds of the writers, from a wish to ingratiate themselves with a people, among whom they were in a manner obliged to spend the remainder of their lives, and from too implicit a reliance upon the statements of the Chinese themselves; but it may very safely be allowed, without incurring the charge of excessive credulity, that these descriptions of the relatively improved state of China, were by no means so devoid of foundation, at the time when they were made, as they must appear at the present day. Most of them were written, from about the middle of the 16th to the beginning of the 17th century; a period when the countries of Europe were far from possessing that superiority to the Chinese, in a variety of respects, which they have now attained. At that time, there prevailed in China, at least the appearance of an universal toleration of religious opinions; while the nations of the West were distracted by the most irreconcilable schisms, and disgraced by the most inhuman persecutions. While the use of silk was introduced, as a curiosity, by the sovereigns of France and England, the peasantry of China were entirely clothed with that elegant manufacture. When the nobility of England were sleeping upon beds of straw; those of China were reposing on silken mattresses. While the European ladies had skewers instead of pins, and had not even a conception of the present ornaments and utensils of their toilet; the Chinese fair had their needle-work, paint boxes, and trinkets of ivory, silver, mother-of-pearl, &c. When the art of improving vegetables by culture was scarcely known in this quarter of the globe, the empire of China was comparatively a garden. It was scarcely therefore to be expected, that the first European missionaries could have been suddenly introduced to the sight of all these arts and luxuries, without being powerfully impressed with the view, and led to express themselves in the most glowing language. Later missionaries continued to speak in the same exalted terms of the pre-eminence of the Chinese, without duly adverting to the rapid progress of the European nations, and the stationary habits of their favourite China men, who, in those very points, in which they then excelled, are now as far below, as they ever were above the inhabitants of Europe. The discovery of this fact has driven many to the very opposite extreme in judging of the Chinese people; and there is at least candour in the remark, that a fair and sober estimate, founded upon actual observation, would present "little to censure, and less to praise." It is unquestionable, however, that the more that Europeans have had an opportunity of personal observation, and the more they have been made acquainted with the state of things in China, the more have proofs accumulated of the inferiority of this boasted and boasting people in these very respects, in which they were most extolled.

Degree of civilization.

Enough, at least, is now ascertained, respecting their state and habits, to warrant the conclusion, that they are but a little advanced, in civilization, beyond the infancy of what is called agricultural society. It may be readily admitted, that they have been among the first of existing nations, who arrived at a certain degree of excellence; but it is not less evident, that they have long remained stationary, or have even in many things become retrograde; and that, when compared with the nations of Europe at this moment; "they can only be said (in the words of Mr Barrow) to be great in trifles, whilst they are really trifling in every thing that is great." The following assertion of Sir William Jones, (if with any, at least with a very little, qualification,) may safely be adopted, and is gradually more generally adopted on the subject. "Their letters, if we may so-call them, are merely the symbols of ideas. Their philosophy seems yet in so rude a state, as hardly to deserve the appellation. They have no ancient monuments, from which their origin can be traced, even by plausible conjecture. Their sciences are wholly exotic; and their mechanical arts have nothing in them characteristic of a particular family, nothing, which any set of men, in a country so highly favoured, might not have discovered and improved."

Physical character.

The natural colour, both of the Tartars and Chinese, is that intermediate hue between a fair and dark complexion called *brunette;* and those, who are exposed to the influence of the climate, especially the women who labour in the fields, have a deeper colour and coarser features. There is said to be scarcely any apparent physical difference betwixt the Chinese and the Tartars, except that the former are rather taller in stature, and more slender in form than the latter, who are in general short, thick, and robust. The Tartar is also more active, hardy, and able to endure fatigue, possessed of greater firmness of character, and displaying greater fortitude under pain. In the countenances of both, the small eye, elliptical at the end nearest to the nose, is a predominant feature; and both, also, have high cheek bones, and pointed chins, which, with the mode of shaving their hair, gives to the head the appearance of an inverted cone. They have small flat noses, and extremely large ears. Their figure is generally large and square[*]; and nothing is conceived more becoming and reputable than a corpulent habit of body. Among the women, there are few that can be called beauties; and the universal features are a short rounded nose, generally a little flattened, lips rather thick, a small and dark brown eye, with jet black hair. The Mantchoo Tartars are considered as in some degree a mixed race, partly derived from the Greeks of Sogdiana; and among them are sometimes seen fair and florid complexions, light blue eyes, straight and even aquiline noses, brown hair, and bushy beards.

The senses of the Chinese are in no respect easily affected, nor their sensations, of almost any kind, very delicate. They are by no means a cleanly people, either in their persons or dress. They seldom change their under garments for the purpose of washing them; never employ the bath, either cold or warm; make no use of soap, and scarcely ever wash their bodies; and even the interior wrappers of the ladies feet are allowed to remain, as long as they will hold together. They carry no pocket handkerchiefs; but wipe their dirty hands upon the sleeves of their gowns, and blow their noses into small pieces of paper, which their attendants have at hand for the purpose. They sleep at night, huddled up under a coverlid, nearly in the same clothes which they wear through the day; a circumstance which, together with their general filthiness, is productive of an abundant tribe of vermin, which the highest officers of the empire will not hesitate to call their attendants, even in public, to take from their necks, when they are troublesome; and which, when caught, they very composedly put between their teeth.

Natural dispositions.

The natural disposition of the Chinese people is mild, chearful, contented, and obliging; their exterior deportment uncommonly decent, and their manners extremely prepossessing. Their external behaviour, indeed, is so much an object of legislature, that there are few instances of abusive language, and still fewer of a quarrel proceeding to blows even among the populace; or if it should go so far, the tearing of each others clothes, and the plucking of each others hair, are generally the most serious consequences. The Chinese, indeed, are declared to be the most timid people on the face of the earth, entirely devoid of personal courage and presence of mind in cases of danger, and capable of being terrified almost into convulsions by the drawing of a sword, or the presenting of a pistol; yet it is said, that suicide by both sexes occurs more frequently among them, than in any other country.

Moral qualities.

The general character of the Chinese, in point of moral qualities, is represented by more recent observers, as a strange compound of pride and meanness, of affected gravity and real frivolity, of refined civility and gross indelicacy, of great apparent simplicity and openness in conversation, attended with a degree of art and cunning, of which an European has no conception. In the Tartar race, there is often a bluntness of manner, approaching almost to rudeness, a considerable frankness of disposition, and a greater adherence to truth and good sense in conversation; but in the real Chinese, there is always a studied complaisance, bordering upon servility, a ready acquiescence in every proposal, and an artful evasion of inconvenient promises, by the most sly pretences and plausible objections. They have no regard for the sacred nature of truth; but will assert or deny, without hesitation, whatever chances to suit the present purpose; and mendacity, in every shape, is affirmed to prevail throughout the whole nation, in a degree which is utterly unparalleled among any other existing race of beings. A natural attendant of this degrading habit, and perhaps also a consequence of the almost daily correction which they receive from the bamboo, is their general servility of mind, and entire want of all sense of shame. There is no principle of honour, or feeling of self-respect, in China; and the fear of detection, or rather of the pain of punishment consequent upon detection, is the great restraining principle and impelling motive both of high and low. A Chinese prince, or powerful mandarin, will commit extortion or oppression, whenever he can do it with impunity, and almost regard it as a matter of right attached to his station. A Chinese trader, or dealer of any description, will cheat and defraud whenever it is in his power, and even pique himself upon his skill in over-reaching, as a proof of his address, and a part of his profession. A Chinese peasant will pilfer and steal whatever is within his reach, whenever he can hope to escape detection; and the whole nation may be affirmed to have almost nothing in view, but their own self-interest and security. Their general character, in short, in point of morals, compared with the minute enforcement of duty by their penal laws, affords an irresistible proof of the utter incompetency of legislative provisions, without the aid of religious principle, to reach beyond the mere external conduct of individuals, or to produce any thing like real social virtue among human beings.

Mendacity.

Inhumanity.

They are extremely deficient even in common humanity and fellow feeling, to which they might rather have been expected to be generally predisposed by their natural timidity and personal sufferings. This cruel and unfeeling disposition appears, not only in the tyrannical proceedings and arbitrary infliction of punishment by men in office, but also in the daily conduct of equals and persons of the lower orders towards each other. The conduct of the soldiery towards those whom they have occasion to apprehend, is often brutal and inhuman in an extreme degree; of which a shocking instance is mentioned by M. De Guignes, that having laid hold of some robbers, whom they had no proper means of binding, they pierced their hands with bamboo reeds, and led them along in this agonising condition. Of the indifference, with which they can look upon human beings in situations of suffering and danger, without making the smallest attempt to afford relief, Mr Barrow relates the following specimen, which occurred during the progress of the British embassy down the Great Canal: Several persons, who had crowded to the brink of the canal, had posted themselves upon the high projecting stern of an old vessel, which broke down with their weight, and precipitated the whole groupe into the water, at the moment when the yachts of the embassy were passing. Though numbers of boats were sailing about the place, not one was observed to go to the assistance of the drowning creatures; but seemed even not to know that such an accident had happened, nor to pay the least attention to the shrieks of the boys, who were floating around upon pieces of the wreck.

Vindictive temper.

Licentiousness.

The Chinese are described also as extremely vindictive, and as indulging their spite, by watching for opportunities of accusing their adversaries to the mandarins; though it frequently happens, that the person accused, equally vigilant and crafty on his part, finds means, by the help of bribery, to make the evil rebound upon the head of his prosecutor. Hence are generated the most fatal feuds and lasting enmities, which frequently terminate by the parties setting fire to each others habitations. The wealthier and higher orders are much addicted to secret licentiousness, and fond of indelicate compositions. Prevented by the restraints of the sumptuary laws, and the dread of being pillaged by those who are in authority, from displaying their riches in expensive equipages and public amusements, they employ their wealth in the private pampering of their appetite, and the secret indulgence of voluptuous inclinations. As it is the law and custom of the country to marry in early life, this sensual disposition seldom appears in licentious intercourse between the sexes, except in the larger cities; but in a plurality of wives and concubines. They are moreover addicted to still more detestable modes of gratifying their passions, without seeming to attach any disgrace to such brutal practices; and many of the officers of state are publicly attended by handsome and well-dressed boys, in the character of their pipe-bearers.

Sobriety.

They are of all people the most exempt from the vice of drunkenness; and, at least, are extremely cautious of appearing before others in a state of intoxication. "I have never met with one of them," says De Guignes, "in this condition; and if merely a little touched with wine, so as to have a flushed and heated look, they appear embarrassed when noticed, and rarely, in such cases, shew themselves in the streets."

Vanity.

They are remarkably full of national vanity; and, in all transactions with foreigners, their self-importance is uniformly conspicuous. However notoriously they may be indebted, in articles of daily use, to the superior skill and science of Europeans, they obstinately persist in regarding all the nations upon the earth, as absolute barbarians in comparison with themselves; and it is said, that a Chinese merchant at Canton was actually subjected to a fine, for attempting to construct a vessel after the English model.

Ceremonious deportment.

Their exterior deportment to each other is so completely regulated by the court of ceremonies, and the omission of the smallest point of etiquette regarded so much in the light of a criminal offence, that even those persons, who are most intimately acquainted with each other, observe, upon meeting, the most stiff and formal behaviour, and perform the stated salutations with the most studied ceremony. Between those, who are members of the same family, and most nearly related to each other, a cold and ceremonious manner is uniformly observed. Every one lives retired and apart as it were from the rest; and nothing, like the easy conversation and unrestrained intercourse of European relatives, exists among them. Even at school, the constrained and ceremonious behaviour, which forms a principal part in the education of their children, prevents them from mingling freely with each other, subdues all their juvenile spirit, and restrains the playful disposition of their age; so that a Chinese youth of the higher class is completely inanimate, formal, and inactive, continually assuming the gravity of age, and carefully observing all the established rules of ceremony.

Filial piety.

Even the virtue of filial piety, in which they are represented as so pre-eminently exemplary, is rather a maxim of government, regulating the external conduct of the people, than a moral sentiment influencing the mind. Entire submission to the will of their parents is the first principle, with which they are impressed; and it is universally inculcated as a positive law, that a father has the same unlimited authority over the properties, persons, and lives of his children, as the emperor possesses over his people; but the whole system of domestic life in China is not considered as greatly calculated to render this civil submission the genuine result of dutiful affection.

It is only the prevailing character, which has been described in the preceding sketch of the Chinese nation; and it may naturally be supposed, that among so numerous a people there are not wanting (though in smaller proportion than in other countries,) individuals possessed of real humanity, integrity, and disinterested minds. Some of their officers of state, even, are represented by the gentlemen of the British embassy, as distinguished by a deportment at once dignified and engaging, and by the most unaffected kindness and condescension; and while, in public, they were under the necessity of assuming all the regulated ceremonious gravity of demeanour, they were in general, in private society, affable, familiar, talkative, and good humoured.

Many of the most unfavourable features in the Chinese character may justly be ascribed to the arbitrary nature of their government, and their peculiar state of society; living in continual fear, and daily suffering the most degrading chastisements, anxious to acquire wealth, which they find to be more powerful than justice or honour, yet obliged to conceal it when acquired; by such means, a people naturally quiet and passive, have been rendered habitually deceitful and unfeeling.

State of women in China.

One striking characteristic of Chinese manners, and of the low degree of civilization, which they have yet attained, is the degraded condition of the female sex, which is affirmed to be much more humiliating and oppressive than among the Greeks in ancient times, or the European nations during the dark ages. It is accounted a species of moral offence in a woman to be seen in the public streets; and when they do occasionally visit a relative or a friend, they must be conveyed to the house in a close chair; while those of them, who cannot command such a vehicle, are sometimes moved about in a covered wheel barrow. They are permitted, indeed, without incurring the charge of impropriety or vulgarity, to visit the temples on certain occasions, to enquire into their destinies; and barren wives, particularly, are encouraged to repair thither as often as possible, that, by rubbing the bellies of the little copper idols, they may conceive and bear children. Those of the lower class, are indeed, permitted to go abroad with greater freedom, but only that they may labour like slaves. They are often seen with an infant on their back toiling at the hardest tasks, while their husbands are sitting at their ease, or pursuing some amusement. They even perform the office of beasts of burden, and are at times employed in dragging the plough or the harrow, which their lazy helpmate holds with one hand, while he casts the seed into the ground with the other. Even in their state of domestic improvement, they possess no privileges or indulgencies; and are not permitted to sit at the same table, or in the same apartment with their husbands. The wives of tradesmen and mechanics generally employ themselves in weaving and embroidering silks, or in painting upon thin gauze the figures of insects, birds, and flowers. But, in the higher ranks, it is accounted a degrading office to handle the needle or the pencil; and the amount of their education consists in a little music and dancing. Utterly unqualified, therefore, to pursue any mental or improving occupation, they employ much of their time in listening to jugglers or fortune-tellers, and generally have recourse to the tobacco-pipe, as the chief expedient for beguiling their tedious hours.

Puny feet.

The most remarkable circumstance, respecting the women of China, is the custom of compressing their feet from their infancy, pushing forward the heel till it be entirely obliterated, and confining the toes with bandages beneath the sole, till they actually grow into the foot, of which they become as it were a part. The large toe is left free, and preserves its natural size; but still the foot makes scarcely any addition to its growth, except a kind of swelling above the instep near to the ankle bone; and the whole is generally so very diminutive, as to enter into a shoe of four inches in length, and an inch and a half in breadth. This practice prevails among all classes in China; and the smallness of the foot is reckoned the most essential point in female beauty, without which indeed they would be looked upon as utterly despicable. The origin of this strange and unnatural custom is wholly unknown; and is conjectured to have been only adopted during the lapse of a few centuries, as it is not noticed in the reports of the earliest travellers into China. It has been attributed to the jealousy of the men, as a method of keeping the females more at home; and is conceived to have been afterwards continued by the ladies themselves, as a mark of superior station. The Tartar women, however, have not conformed to this custom; but, on the contrary, have rather large feet, with wide square shoes; and both walk and ride abroad with greater freedom.

Marriages.

The women are invariably sold at marriage, and are not permitted to exercise any choice of their own. The bridegroom bargains with the parents or other relatives; and the highest bidder is commonly preferred. At the same time, he is not allowed to see his intended wife, till she arrive in procession at his gate, shut up in a close chair, of which he then receives the key; and, should it happen, upon his opening the door of the vehicle, that he is not pleased with his bargain, he is at liberty to return her to her friends, upon condition of forfeiting the purchase money. But the lady has no remedy or option, and must pass to the highest purchaser, or to the person whom her parents choose to prefer. Mutual affection, therefore, between the sexes may be considered as in a manner unknown in China; but every one hastens to procure a wife, because such is the law and custom of his country. He sets out to purchase his future partner, as he would look out for some necessary article of household furniture; and she continues on her side, to act nearly as inanimate and motionless a part, as if she were nothing else. She neither considers it as any indignity, nor expresses any feeling of jealousy, though a second or a third wife should be brought into the house; but is contented with presiding as the first female in the family, and with being called mother by all the children. Upon the death of the husband, the widow, if a person of rank, is honoured by preserving her state of widowhood; and it is very rarely the case, that she enters a second time into the married life. But, in the lower classes, the relations of the deceased generally dispose of the widow to another husband, that they may gain something by pocketing the price which she brings.

Marriage ceremony.

The marriage ceremony is sufficiently simple, and consists in little else than the procession of the bride to the gate of the bridegroom, and his reception of her into his house. The bargain, as has been mentioned, is concluded between the relations on each side; and the acceptance of the marriage presents is accounted a sufficient evidence and ratification of the contract. On the day appointed, the bride is conveyed in a close palanquin to her future residence, escorted by domestics and female slaves bearing presents from her family to her intended husband, preceded by musicians of different descriptions, and followed by her friends and relations. One of her nearest kindred carries the key of the palanquin, and commits it to the bridegroom upon reaching his house, who conducts his spouse to the presence of his parents, before whom they both prostrate themselves, in token of dutiful submission. Afterwards, the two parties partake together of food, and drink wine out of the same cup. The male attendants are entertained in one apartment, and the females in another; and on these occasions, the Chinese are often extremely extravagant, so as frequently to impoverish themselves during the rest of their lives, by the expences attending the marriages of their children. The wives continue their former retired life, seeing only their husbands or near relations, occupying themselves with the internal economy of their households, and devoting the greatest attention to the care of their children.

Birth and names of children.

The Chinese give great entertainments at the birth of their children to their friends, who on their parts offer congratulations and presents on the occasion. On the third day, the child is washed with great ceremony, when, among other meats and presents, the company eat painted eggs given by the grandmother. There is in every household a family name, which is never changed; and at the birth of a male, another name is given called *the little name*, which, however, the daughters never receive, but are distinguished simply by *first, second, third* placed before their family appellation. The *little names*, or names thus received at their birth, are used in signing letters; but no one addresses another by these designations. In entering upon their education, they receive from their teacher their *school name*, by which their master and school fellows always address them. Upon leaving school, they drop this name, and assume another at marriage, which they ever after retain, unless they obtain some honourable office, when they take an additional name, by which they are thenceforth addressed.

Infanticide.

A parent in China possesses the most absolute authority over his children; and, though he should occasion the death of a child by severity of punishment, is subjected only to the penalty of 100 blows, reduced in reality to forty. The practice of infanticide has long been regarded, as one of the deepest stigmas upon the character of the Chinese, and as the most unequivocal proof of their unfeeling dispositions. Though this barbarous and unnatural crime be not actually sanctioned by law in China, it is at least tolerated and overlooked. It is a part of the duty of the police at Pekin to go their rounds with carts at an early hour of the morning, to pick up the bodies of the infants, that have been thrown out into the streets, in the course of the night, and to carry them, without enquiry, to a common pit without the city-walls, into which they are said to be thrown promiscuously, whether living or dead. It has been calculated, that nearly 20,000, chiefly female infants, are annually collected in this manner throughout the empire; but, at the same time, it is admitted, that a great proportion of these have not been destroyed by their parents. As the law requires, that every corpse, whether young or old, must be carried to a place of burial, which is generally at a considerable distance from the city, and as funerals in China are attended with very heavy expences, many of the infants, found in the streets, are understood to have been dead born, or to have died in their early months, and to have been disposed of in this manner, as the cheapest mode of burial. M. De Guignes, however, positively denies the supposed frequency of infanticide among the Chinese, and strenuously maintains, that it does not happen in a greater number of instances, than might be conceived to arise in so vast an empire, from the extreme misery and poverty, to which the lower classes are often reduced by the dreadful famines which repeatedly occur. Some of his presumptive reasonings, however, against the fact, such as, that the Chinese account themselves dishonoured when they leave no family to perform their funeral rites, and to perpetuate their memory in the hall of ancestors; and that, in this view, they are often known to adopt the children of others when they have no offspring of their own; are by no means sufficiently conclusive on the point, as it is never contended, that a Chinese parent destroys *all his children*, but only those, for whom he thinks himself unable to provide. But what he affirms as facts, and advances upon his own personal observation, is more deserving of credit and consideration. There are in every city, he informs us, houses prepared to receive the children who are exposed; and thither all these, who are found alive, are carefully conveyed and brought up. "I have traversed China throughout its whole length. In travelling by water, I never saw an infant drowned. In my route by land, I have passed through the cities and villages early in the morning, and have been upon the roads at all hours of the day, and I never yet perceived one child exposed or dead." He affirms, farther, that the Chinese tenderly love their children; that the women are remarkably careful to preserve them from accidents; and that they testify all the usual distress of a mother, when their infants are in danger of perishing. "From all that I have said," he concludes, "I will not affirm, that infanticide does not take place in China; but I will contend, that it is not more common there, than in any other parts of the globe."

Slaves. In ancient times, there were no slaves in China, except those who were taken prisoners in war, or condemned to servitude by the laws. Afterwards, in times of famine, parents were frequently reduced to the necessity of selling their children; this practice, originating in the pressure of necessity, has continued to exist, and even become common, from mere motives of sordid avarice. It is chiefly female children, who are thus disposed of, and who are educated in music, dancing, and similar accomplishments, that they may be sold as concubines to the wealthier classes, or produce profit to their purchasers, from the wages of prostitution. Frequently, however, both male and female slaves are employed as domestics; the latter, generally accompanying the young women of the family when they marry, and the former being employed as labourers or artizans. Boys are purchased, also, by the players to be instructed in their art, and to recruit their number. A person may also sell himself as a slave, when he has no other means of succouring his father; and a young woman, who finds herself destitute, may, in like manner, be purchased with her own consent. The prisoners of war are the slaves of the emperor, and generally sent to labour on his lands in Tartary. Except in the case of those, who are sold by the sentence of the judges, and the concubines of a mandarin whose goods are confiscated, there are no public markets or sales of slaves in China; and the condition of persons of this class is very different from that of the negroes in the West India colonies, better protected by the laws, and treated rather as servants or even as children, than as beasts of burden.

Eunuchs. Eunuchs were formerly extremely numerous in China; and, as appears from the history of the empire, frequently exercised no small degree of political influence. At the Tartar conquest, they were reduced from ten thousand to one thousand, and afterwards to three hundred; but, since that period, they have again increased to about five or six thousand. They are employed chiefly in the imperial palaces or habitations of the grandees; where they perform the mere menial offices of sweeping the rooms, arranging the furniture, watching the gates, keeping the gardens, and serving the women. Those, who were observed about the emperor's palace at Pekin, were generally large and robust in their persons, but distinguished by an uncommon shrillness of voice. They have no beard, or soon lose it; and, though possessing plump countenances in youth, they become very ugly and wrinkled as they grow old. Many of them have wives, and adopted children, to whom they bequeath their property.

Mode of living. The mode of living among the lower orders in China is miserable in the extreme. Two or three jars, a few basons of coarse earthen ware, a large iron pot, a frying pan, and a portable stove, are the chief articles of furniture in their possession. They neither use tables nor chairs, but at meals all the family sit upon their heels round the large pot, with a bason in every one's hand. They take the rice from the pot with a spoon, and put it into the bason, which they hold in the left hand close to their mouths; and then, with two slender sticks, or porcupine quills, between the two first fingers of the right hand, they throw the food, with great expedition, into their mouths. Their food consists chiefly of boiled rice, millet, or some other grain, with the addition of onions or garlic, or some other vegetable, especially the Pe-tsai, a kind of insipid cabbage or beet, fried in oil, which is most esteemed when in a rancid state; and sometimes season their food with a wretched kind of ragout made of shrimps pickled in brine. They have little milk, no butter, cheese, or bread; and, unless in those places where fish abounds, a morsel of pork is the only animal food, which the poor can afford to taste, as a relish to their rice. They are little scrupulous, however, as to the articles of their diet; and rats, frogs, worms, and dogs, are all excellent food to a Chinese. The latter are reared and fed for the purpose, and are said to be neither unpleasant nor unwholesome. Those who were employed in the conveyance of the British embassy thankfully picked up the refuse of the provisions; and even boiled again the tea leaves which had been used. There is nothing so filthy, that those who ply in boats upon the river at Canton will not use as food; and the dead hogs, which are thrown over board, and which float when they begin to putrefy, are considered by these poor creatures as a most valuable prize, and often furnish occasion for serious contests. It is said, also, that the Chinese, when

Character and Manners.

they get on board of any foreign ship, are apt to give pepper, or some such article, which proves fatal to the hogs, that they may get them when dead; and it is certain, that multitudes of these animals die in the possession of Europeans, during their stay in China. Rice, however, is their great staff of life, and its name, Fan, occurs in almost every expression, which relates to food. A meal is named tche-fan, *to eat rice*; breakfast is called tsao-fan, or *morning rice*, and supper, ouan-fan, or *evening rice*. Their chief beverage is bad tea, boiled again and again, as long as the leaves will yield the smallest taste or tinge to the water; and this is taken without milk, or sugar, or any other ingredient whatever, except a little ginger in cold weather. The principal use of the tea is to purify the water, which, in that level country, is extremely impure, and which the Chinese never use till it has been boiled. They take little care, however, to procure it of a good quality, but make use always of the nearest pond, and trust to the effects of the tea to correct its impurities; and especially to the leaves, which are supposed to carry down the sediment to the bottom of the vessel. They make at least two regular meals in the day, one about 10 o'clock forenoon, and another about 4 or 5 in the afternoon; but it was observed, that they generally had their frying-pans on the fire by four o'clock in the morning, and were always cooking something or other for the belly.

The diet of the wealthy in China is as plentiful and sumptuous, as that of the lower classes is poor and meagre. The substantial articles of their ordinary meals are rice, pulse, pork, mutton, poultry, and fish. They seldom use beef, which is said, however, to be excellent at Wampoo; and their mutton also is good, but abounds only in the northern provinces. Ducks and game are in daily use; but the flesh of young pigs, which is said to be extremely light and wholesome in China, is the most common species of animal food at the tables of the higher orders. The Tartars make regular use of ass, and especially of horse-flesh, which is said to be sold at a higher rate in Canton than young pork. The flesh of hare and of the stag is much used at Pekin; and the most esteemed part of the latter animal is the tail, which is reserved for the table of the emperor, and which sometimes sells for 30 or 40 taels. It is said to have the taste of rancid tallow. The wealthy Chinese seek after the most nourishing and invigorating diet with great avidity, and at whatever price. The greatest delicacies are the most gelatinous substances, the paws of the bear, the fins of the shark, the sinewy parts of the stag and other animals, the nests of a particular species of swallow brought chiefly from Cambodia, and a kind of fucus or sea-plant. Of this last they make a very nourishing and refreshing jelly, which is mixed with sugar and orange juice. Their bread is made without yeast into small cakes, and is very light and white, but seldom sufficiently baked. They use a variety of vegetable substances in the form of pickles, particularly Pe-tsai, already mentioned, onions, ginger, and the young shoots of bamboo. They have a number of fruits also preserved by sugar, especially a preparation from the flour of beans, which is used sometimes in a liquid, and sometimes in a solid form, and which is represented as remarkably insipid. They are very fond of eating their fruit, after it has been cooled upon ice; and this luxury is so abundantly collected in the city of Pekin, that even the poorer classes are able to procure it. Their cookery is said to be sufficiently good, their soups and vermicelli particularly excellent, and their pastry, made from the flour of buck-wheat, unusually light, and as white as snow. Their dishes are chiefly in the form of stews of fish, fowl, and meat, sometimes separately, and sometimes promiscuously, mixed with various vegetables and sauces; and their drink at table is either tea or an ardent spirit distilled from millet or rice, which they always drink in a hot state, and which is said to resemble burnt brandy. They eat very plentifully, and rather voraciously, at meals; and throughout the day are constantly eating pastry and fruits, sipping spirituous liquors, smoking tobacco, or chewing betel and areca nut.

Character and Manners.

Prices of food.

The following are the prices of some of the principal articles of subsistence at Pekin, according to Mr Barrow.

Beef, per pound,	6d.
Mutton,	8d.
Pork,	8d.
Bread,	4d.
Rice,	1½d. or 2d.
Wheat flour,	2½d. or 3d.
Eggs, per dozen,	1s. 0d.
Fowls, each,	from 2s. to 3s.
Tea, per pound,	from 12s. to £1, 10s. and yet not so good as may be purchased in London at 6s. per pound.

Coals.

Coals, brought from the mountains of Tartary on the backs of dromedaries, are extremely dear, and are generally pounded, mixed with earth, and dried in the form of bricks, when they burn without flame, but yield a heat sufficiently strong for their small stoves.

Price of labour.

The price of labour in the same city is nearly one shilling per day to the best employed mechanics; but hired servants may be had at the rate of one ounce of silver, or 6s. 8d. per month, and sometimes merely for their subsistence.

Dress.

The clothing of the Chinese in ancient times, consisted of long and ample robes, with immense sleeves reaching to the ground, and a large quantity of hair gathered up under their caps. But they have been compelled to adopt the habits of their Tartar conquerors; and, like them also, they shave the hair from their heads, except a single tress or tuft, which they form into a long plaited queue, called Penzé. Many of the lowest class have scarcely any other clothing, than a single pair of cotton drawers, and straw shoes; but the dress of the majority consists of a jacket or frock of black or blue cotton, wide cotton drawers, straw hat and shoes, frequently without any covering for the legs, and sometimes with stockings of coarse cotton cloth. The better sort wear a kind of velvet cap on the head, of blue, black, or brown silk, a jacket of cotton cloth or European camblet, buttoned close round the neck, and folded across the breast, with sleeves remarkably wide; and frequently, instead of drawers, they have quilted petticoats and black sattin boots. In those provinces where silk is abundant, the people are clothed chiefly in that article, as all the Chinese proceed upon the principle of consuming their own immediate products, and of receiving as little as possible from other districts. The dress of the more wealthy consists of a number of garments. Besides a robe of thin coarse silk, nearest to the body, by way of a shirt, and a vest generally of the same stuff, with drawers, or quilted petticoats, they have commonly three and at least two upper garments. That which is next to the vest is without sleeves, but reaches nearly to the feet. The one above this is equally long, and has the sleeves very wide towards the shoulder, but narrower towards the wrist. The outer garment is not so long, reaching only to the calf of the leg, and has sleeves of a moderate width. These two upper robes resemble the

European night-gowns; and are fastened before with small round gilt buttons, which catch into little strings on the opposite side, so as to make the coats double upon the breast. Beneath their upper robe, they have a girdle fastened round the body, from which they suspend a watch, a knife, and a purse or pouch, generally containing a tobacco-box. They suffer their neck to remain uncovered during summer, but defend it from the cold in winter, by a collar of peltry, silk, or velvet. Their summer cap resembles an inverted funnel, lined with silk, with a tuft of red hair, or raw silk, on the top, hanging down on each side; but the winter bonnet is surrounded with a band of peltry. Instead of the bonnet, they frequently wear at home, a kind of under-cap of embroidered silk, sometimes ornamented with a pearl in the front. Their drawers, made of linen or silk, resemble generally those of Europeans. Their stockings are of quilted silk or nankeen, appearing above the boots, and bordered at the top with a ribband of silk or velvet. Their shoes come high upon the fore part of the ankle, and do not require to be tied. Their boots are made of black satin or leather, and do not reach higher than the calf of the leg. They are extremely wide, and are frequently made to serve the purpose of pockets, holding a fan, papers, &c. The soles are remarkably thick, composed of several folds of strong paper, covered with one of leather. In winter, the Chinese put on an immense load of clothes, sometimes, says Osbeck, to the number of thirteen or fourteen robes; and De Guignes declares, that he has seen them so stuffed out with clothing, that they could scarcely make their hands meet.

Dress of the women.

The dress of the women in the lower classes differs little from that of the men, consisting generally of a blue cotton frock reaching to the knee, a pair of wide trowsers or petticoats of red or yellow cloth, reaching to the calf of the leg, and there drawn very tight, to display the ankle and foot. The ankle is thick and swollen in proportion as the foot is diminutive; and is also bandaged with rollers of party-coloured cloth, ornamented with fringes and tassels; while the little shoe is almost covered with tinsel and tawdry appendages. The hair is screwed up close behind without taste, and folded into a ridge or knot across the crown of the head, where it is fastened by two bodkins of silver, brass, or iron, placed conspicuously behind, in the form of an oblique cross. A part of the hair of the unmarried women, however, is suffered to hang in short tresses round the head, and that of a very young girl is left still more dishevelled. The women of Pekin, particularly, adorn their hair with artificial flowers of a red, blue, or yellow colour, generally resembling asters; and those of the province of Kiang-nan wear a very peculiar cap of peltry or black satin, with a triangular peak in the front descending to the root of the nose, and adorned in the middle of the forehead with a crystal button. In most places they wear hats of different forms, commonly made of straw, completely surrounded with a fringe of blue cloth. They daub their face and neck with white paint; tinge the eyebrows black, in the form of an arch; and place a spot of deep vermilion, about the size of a wafer, in the centre of the lower lip, and at the point of the chin. They are generally of the middle size, and slender figure, with a short nose, long eyes, and little mouth; but their large teeth are uniformly yellow from the constant use of tobacco and betel, and their skin, from the early use of paint, soon acquires an ugly appearance. It is a piece of dress, both of men and women of rank, to suffer the nails of the left hand, especially of the little finger, to grow to an extraordinary length, in order to prove their gentility, and to distinguish them from labourers and mechanics. M. De Guignes saw a mandarin, whose nails were nearly six inches in length; and a physician, who had brought them to the length of nine, ten, and even twelve inches. The nails are thus kept extremely clear and transparent, and at night are carefully inclosed in bamboo cases. The Chinese dresses are generally cheap, chiefly formed of cotton, which grows in all the provinces, or of silk, which is in some places almost equally abundant; so that the complete clothing

	L.	s.	d.
Of a peasant costs about	0	15	0
Of a tradesman	3	0	0
Of a mandarin	10	0	0
But a mandarin's dress of ceremony	30	0	0
And those which are enriched with embroidery, and gold or silver tissue	200 or 300	0	0

Mode of living.

Entertainments.

The Chinese rise at a very early hour, and the streets in their cities are completely crowded at day-break. They retire to take their evening meal at five or six o'clock, and go to rest with the setting sun. They have few social meetings among themselves; and even the young people never assemble together for the purpose of athletic exercises, or exhilarating amusements. To play at games of chance is the chief object of an occasional company; and a kettle of rice, a cup of tea, or a pipe of tobacco, forms the only entertainment among the great body of the people. The higher classes give feasts and entertainments on particular occasions; but, in these, nothing approaching to conviviality or chearfulness appears; and almost every action, motion, or look, is regulated by the coldest forms of ceremony. The guests do not assemble around the same table, and partake of the same dishes; but a number of small tables are arranged in a line, each of which often accommodates only one person, generally two, and rarely more than three. This division of the company into small parties, does not produce any greater freedom in eating, drinking, or conversing; but every one must wait for a particular signal or ceremony, at every drop or morsel which he puts into his mouth. All eyes are constantly directed to the master of the feast, to observe his motions, and to eat or drink after his example. The repast begins with drinking to the health of the host; and the polite manner of paying this compliment is to lift the cup in both hands as high as the forehead, after lowering it again to carry it to the mouth, and after drinking deliberately to turn the cup downwards as a token of its being emptied. Every one's portion of the different dishes is measured out according to his rank, and placed on the table before him; and whatever remains after he has eaten, as well as the portion of any one who has been prevented from attending, is sent in procession to his house. Several changes of plates and dishes takes place, and two or three cups of wine or tea are drunk during the repast; and all the guests rise for a little, before the desert be served up, when each resumes his place. In this manner, four or five hours are commonly employed, during which period a play or dance is sometimes exhibited for the amusement of the company. Upon leaving the house, every one makes a small present in money to the domestics; and next day sends a note of thanks to the person, who gave the entertainment.*

---

* "They swallow their food," says De Guignes, "in a gluttonous manner; and drink indiscriminately out of all the cups, without caring whether any one has used them before. Upon leaving the table, they prove, by every possible mode, that they have dined well; and even account it a point of politeness to give, in this manner, to the master of the house, marks of their *full* satisfaction."

Visits and salutations. The external expressions of civility and respect are exactly regulated and strictly inculcated by the laws of China. But it is the form, which they study, without either the ease of good breeding, or the sincerity of real kindness. Persons of all ranks prostrate themselves in the presence of the emperor, and address him in a set of phrases, which are appropriated to him alone. When any one presents a request to a mandarin of high rank, he bends the knee, inclines his head three times towards the ground, and, in this posture, communicates his wishes; but, should the petitioner be a person above the common order, he is generally desired to rise, and retiring to one side, he makes his speech in an upright position. In speaking, also, to persons of rank, it is a part of polite behaviour, to place the hand before the mouth, and to incline the body in a respectful manner. In ordinary cases, the mandarins avoid as much as possible to meet each other; but, when two of them chance to meet, the inferior leaves his palanquin, and makes a profound reverence to the other; or if they are of equal rank, they both remain in their chairs, and make a salute as they pass. When one of the lower order meets a mandarin, he does not presume to salute him; but quickly turns to one side, and places himself erect, with his head inclined, and his arms hanging by his sides. To the aged, to parents, and to elder brothers, particular respect is shewn; and they always occupy the most honourable place; which, among the Chinese, is the right hand, and, among the Tartars, the left. When two Chinese of equal rank salute each other, they bend themselves towards each other, join their hands, and repeat the words Tsin-tsin, or Tsin-leao, *I salute you*. On such occasions a common expression is hao-hao, *good, good*, or ya-fan, *have you eaten your rice*, a competent supply of which article is always a principal ingredient in the comfort of a Chinese; but to persons of superior station, the proper title of respect is Lau-yé *old sir*, or *old gentleman*, as age is always the chief object of reverence and esteem. When one Chinese wishes to pay a visit to another, he first sends in his compliments with his name contained in a billet of red paper folded like a screen, with a small triangular piece of gilt paper on the last leaf. These visiting cards or tickets, are of a certain size, colour, and degree of ornament, according to the rank of the parties; and the card of the viceroy of Pe-tche-lee to Lord Macartney, is said to have contained as much crimson-coloured paper, as would have covered the walls of a room of moderate size. If the person, visited, wishes to decline the visit, he returns the billet with a request, that his friend will not trouble himself to descend from his palanquin, and then sends to him a similar card; and the more hurry in dispatching it, the greater the respect. If, however, he is disposed to receive the visit, and if the visitor be of equal rank, then a multitude of civilities are interchanged. The great display of ceremony takes place in entering the gate, the stranger consenting only, after much entreaty, to pass through the middle gate, while the other enters by one of the side doors. Upon entering an apartment, a seat is offered, which the master of the house, at the same time, slightly wipes. When once seated, they keep themselves erect, with their hands upon their knees, their feet equally distant from the chair, and their whole appearance sedate and composed. Their conversation is remarkable for insipidity and sameness, turning chiefly upon the affairs of the neighbourhood, the injustice of the magistrates, the tricks and stratagems of the merchants and mechanics. Tea is always presented at these visits. The leaves are put into a porcelain cup, boiling water poured upon them, the cover put on, and the cup presented in a bason or copper server. The cup is lifted with both hands, and slowly emptied. If a present accompanies the visit, it is committed to the servants, and a note of the articles, of which it consists, accompanies the card. The master of the house examines the contents after the departure of his visitor; accepts the whole or a part; and, in the latter case, he writes in a note what he has retained, which he sends with the portion returned. Sometimes they merely send a list of the presents intended, when the person addressed marks the articles, which he is willing to accept, sends back the note, and then receives the objects specified. Even their letters are attended with similar formalities; every one consisting of nine leaves, beginning at the second; folded within an envelope, covered by a strip of red paper; then inclosed in a paper bag, which is sealed at the mouth, and upon which is written the name, quality, and residence of the person to whom it is sent.

Carriages. No person of any distinction can with propriety walk on foot, upon a visit or short journey; but must make use of a palanquin, a sedan-chair, a wheel-carriage, a horse, or mule. The palanquins of the mandarins are covered with green cloth, and the chairs of the ladies are closely shut. Among the carriages in use are large wheel-barrows, or small carts with one wheel, pushed along by one person; and these are sometimes provided with a sail, which appears to have very little effect, and to be attended with greater inconvenience than benefit. These wheel-barrows are used chiefly for carrying baggage, and also for conveying the women and children. In the latter case, they are commonly covered with a kind of mat to shelter the family; and, when heavily loaded, an ass is sometimes yoked in front, which answers better than the sail. Their travelling carts are narrow, clumsy, and ill constructed, with small wheels, without spokes. They resemble the hearses of Europe, though not above half their length; are without any seats, or springs, of which the Chinese appear to have no idea; and the only improvement, with a view to diminish the jolting, is to place the wheel well back, or to put a third wheel in the middle, between the two at the sides. They are always covered, generally lined with blue cloth, and sometimes furnished with black cushions. They are commonly open in front, with a square window at each side; but sometimes they are shut before, and have the door at the side. The driver sits at the entrance in front; and they have only one horse, even in some of a considerable size. When the Chinese ride on horseback, they use commonly wooden saddles, and a simple cord by way of bridle. Instead of horses, they prefer mules, because their step is more sure, and their motion more easy, because they are capable also of subsisting upon less nourishment, and of enduring greater fatigue. They are not fond of riding at great speed, but rather set out early, and travel slowly. In the northern districts, numbers of dromedaries are used as beasts of burden, which are remarkably gentle, and generally follow one another in files, a driver merely leading the foremost with a cord.

Games and amusements. The Chinese, of all ranks, are passionately fond of gaming; and whenever they come together, whatever be the occasion, they seldom separate without a trial of their good fortune. For such opportunities, a Chinese is always provided with a pack of cards, or a pair of dice in his pocket. The former are long and narrow, smaller in size, but more in number than those of Europe. The latter are exactly similar to ours, and are frequently carried in a cavity, made for the purpose in the handles of their knives. When the party are not provided with either of these articles, they have recourse to their fingers, with which they play a game named Tsoi-moi, and which is extremely common among the lower classes. At this game the closed hand is counted nothing, and each finger, when elevated, is reckoned one. The players sit opposite to each other; one of them names a particular number, suppose six, and holds up as many fingers as he thinks proper, suppose two; to which his opponent replies by raising four fingers, the number required, together with the two fingers of the first player, to complete the number announced. At this game, they play remarkably quick, and keep bawling at a great rate. It is frequently introduced among the middle classes of the community, at their entertainments; and the person who loses, or mistakes the number, is obliged to drink a cup of wine or spirits,—a species of forfeit which in some countries might incline the player to lose, and which even the Chinese sometimes continue till they become unable to distinguish the fingers; but in these cases they generally remain in their place, that they may not be seen in this flustered state. Persons of a better station play also at a kind of chess, a game which is much esteemed in China, and in which the number of pieces are the same as what are used in Europe, but both the names and moves are considerably different.

Chinese chess.

The board contains 62 squares; but the pieces are placed at the intersecting points, and not within the spaces formed by the lines. These pieces are, a general, placed in the middle of the line next to each player, having on each hand an adjutant, an elephant, a knight, and a chariot. In the third line, and before each of the knights, is placed a bombardier; and in the fourth line are five soldiers, one in the front of each chariot and of each elephant, and the fifth in the front of the general. The general never leaves the points of intersection formed by the four squares immediately adjacent to his place; the adjutants move like our bishops; the knights also like ours; the chariots and bombardiers like our castles, except that the latter take a piece only when there is another before it; and the soldiers move like our pawns, straight forwards, taking, however, only in that direction, and not in an oblique manner. They play also at domino, and a species of draughts, in which there are 360 squares, with a number of men on each side; and in which the game consists in shutting up the adversary, by occupying the greater part of the spaces. Contrary to the assertion of the French missionaries, the spirit of gaming, especially at games of chance, is so prevalent, that almost every bye-corner in the streets is occupied by a groupe of gamblers; who often continue whole days at play, and sometimes carry their infatuation to such a height, as to stake their wives and children upon a throw of the dice. The higher classes are passionately addicted to the barbarous amusement of cock-fighting, or rather quail-fighting; and have even employed for their sport in a similar manner, a species of locusts, which fight with such ferocity, as seldom to quit their hold of each other, without bringing away a limb in their gripe. These little insects are fed with great care, each in a separate bamboo cage; and it is said, that, during the summer months, scarcely a boy is to be seen without his cage and grasshoppers. Dancing is rather a spectacle or pantomime in China, than an exercise of individuals for their own amusement; and consists merely in a set of marches and evolutions, sufficiently whimsical and wearysome. They have frequently plays represented, even at their private entertainments; and a stage is prepared in an instant, with merely a table and a few chairs placed in front of a large hanging, in which are two openings for the passage of the actors. The mandarins have generally rooms for the purpose; and the people often fit up parts of the pagodas as theatres, or erect them across the streets, from one corner house to the other, where the multitude spend whole days in witnessing the exhibitions.

Funerals.

One of the principal and uniform cares of a Chinese, during life, is to preserve his body from being maimed, and to die in possession of all the members, which he received from nature. Some of them, it is said, carry this precaution to such a length, as to preserve all their hair and nails, which have been cut, that they may be carried with them to the grave. His next object is to provide a proper burying ground for himself and his family; and, after ascertaining from a Bonze, or some oracular temple, the most fortunate situation, he spares no expence in the purchase. The burying grounds are always situated at some distance from the towns or villages, generally upon an eminence; and, as one corpse is never interred in the same grave, where another has been laid, at least as long as the smallest vestige of the former remains; these burying places occupy an immense extent of ground, planted with cypress or weeping willows, and sometimes provided with a pagoda and idol images.*

The funeral rites are attended with enormous expence in China; and the most showy articles, to be found for sale in the large cities, are coffins for the dead. They are made of planks, from three to six inches in thickness, very closely joined; raised like a trunk on the top, and generally convex, also, at the two ends. They are sometimes made of the more precious kinds of wood, very richly ornamented, and cost from 300 to 600 dollars; while that of a person in ordinary wealthy circumstances is seldom procured for less than from 10 to 15 or 20. It is a common practice for individuals to purchase their coffins during their lives; and it is frequently the son who presents one to his father, which is always the more highly valued, and shewn with greater complacency to every visitor, in proportion to its magnificence. When brought forth for use, a layer of lime is put into the bottom; the body deposited in full dress, with a cushion under the head; the vacant spaces completely filled with lime and cotton; and the lid then fastened down with the utmost exactness. The whole coffin is generally pitched within and without, sometimes covered with varnish, and whitened externally. In this state they often remain in the houses a considerable time, without the smallest odour being perceived; and, while the body of a parent is thus kept uninterred, during the period of mourning, his children, go every day to weep at the side of the coffin. In ordinary cases the corpse is laid in a room hung with white cloth, with a covering of the same colour thrown over the coffin, and a table placed before it, with candles of perfumed materials. In this situation it remains several days in the house previous to interment; and all, who come to show their respect to the memory of the deceased, are entertained by some of the relatives with tea and other refreshments. On the day of the funeral, after the relations and friends are assembled, the procession is opened by musicians, who are followed by several persons carrying the figures of various animals, the insignia of the rank of the deceased, small pagodas, parasols, white and blue flags, with vessels of perfumes. Next walk a party of Bonzes, immediately before the coffin, which is carried by 4, 8, or even 20 men upon a litter, which is sometimes surmounted by a canopy. Behind the body are the children and near relations, with robes of coarse linen over their clothes, and caps of the same stuff. The eldest son walks with his body bent forwards, leaning upon a staff, and is generally supported by two friends, one on each side, who prevent his repeated attempts to tear his hair and his face. These are followed by the friends and domestics; and last of all, at a little distance behind, appear the women, on foot, or in palanquins, with dishevelled hair and broad white fillets round their temples, dressed also in the same coarse linen as the men, and bursting at intervals, as with one consent, into lamentations and tears. These processions, in the case of persons of distinction, sometimes extend more than a mile; and whenever they approach a bridge, or temple, a halt is made, a few images of tin-foil are burned, a parcel of crackers are fired, and a flourish is sounded by the gongs and other musical instruments. If the deceased has not previously fixed upon the precise spot for his grave, the relations consult the Bonzes as to the place, which is most likely to prove agreeable to his manes, and which is generally a dry, well-aired, and pleasantly situated spot. The better that all these matters are arranged, the more does it gratify the deceased, and the more do his surviving relations prosper. So much, in their opinion, depends upon the proper situation, especially of a father's grave, that when a family becomes unfortunate, it is not uncommon for them to raise the dead body, and to seek a more agreeable spot, that, if possible, the malignity of their destiny may thus be changed. When the coffin is entirely covered with earth, libations are poured out; perfumed candles and paper flags placed around and upon the tomb; and the figures of men, clothes, and horses, all cut in paper, are burned upon the spot, in the firm persuasion, that the objects, thereby represented, will attend the deceased into the other world. This last mentioned ceremony is supposed to have been substituted in place of a barbarous custom formerly practised, especially among the Mantchoo Tartars, of sacrificing the horses, slaves, and concubines of deceased princes and mandarins at their graves; and it is certain, that so late as the year 1661, at the death of one of the wives of the Emperor Shun-tchee, thirty persons, and an immense quantity of gold, silver, silks, and articles of furniture, were burned along with the body. After the ceremonies are finished, the company rest themselves in tents erected at a little distance from the grave, where they pronounce the *eulogium* of the deceased, and partake of the meats offered to his memory; and then returning to the grave, prostrate themselves before it, and exchange salutations with the chief mourner, in profound silence. The period of mourning is fixed by law, according to the degree of relationship; and the time appointed for a father or mother is three years, which is reduced to 29 months, during which period the mourner can hold no public office, unless the Emperor expressly requires the continuance of his services. During the earlier months of the time of mourning, the dress is made of a coarse reddish cloth made of hemp, with a cap of the same, and a cord round the middle. During the second period, the robe, cap, and shoes are white. During the third, the dress may be of silk, but the shoes must still be white or blue. Both during the period of mourning, and long after it is expired, the children and other near relations frequently go to weep at the graves of their deceased parents. Every year, at the third moon, they regularly visit the abodes of the dead to repair the tombs, and to renew, in part, the ceremonies of interment; and particularly, in the spring season, the whole community assembles in the hall of ancestors, to perform similar rites in honour of their respective departed fore-fathers. In this hall is placed a tablet about five or six inches long, called Shin-tchoo, or *abode of the spirit*, on which is inscribed the name and rank of the deceased, with the year, month, or day of his birth and his death. Besides making prostrations and presenting offerings before this tablet, the relations prepare a piece of silk, about two yards in length, upon which they write the same inscription as upon the tablet; and believe, that, by this ceremony, they invite the spirit of the deceased to take up his abode in their habitations.

---

* See under the head of Architecture in this article, some account of the Chinese cemeteries.

NATURAL HISTORY.

The empire of China, which is so very extensive, may naturally be supposed to exhibit considerable varieties of soil and climate. The prevailing qualities of each in the several provinces, have already been noticed in the introductory part of this article; and it is only the general features of the country, which remain to be mentioned.

Climate.

The temperature of the atmosphere is, generally speaking, rather warm than cold, and is much affected by the direction of the winds, which almost make the circle of the compass during the course of the year. They blow from the north, and north east, in October, November, December, January, February, and March, and during this period the weather is rather cold; from east and south-east, in April and May, when it is cool; from the south and south-west in June and July, when it is hot; and from the west in August and September, when it is extremely sultry and oppressive. The coldest months are November, December, and January, and the hottest, July, August and September. Ice is sometimes found at Canton during the winter, of the thickness of a dollar; but snow is never, or at least very rarely, seen in that city. The air is generally dry during the north, moist during the south, and clear during the west winds. The north winds are the most violent, and the south the most feeble; those from the east are strong, and those from the south and south-west are more moderate. It is always calm weather when the winds are about to change, and the storms take place commonly in July, August or September. These hurricanes, called Tay-fun, continue for eighteen or twenty hours, coming in sudden gusts accompanied with rain, always preceded by the sinking of the barometer, and generally ceasing whenever the thunder breaks. The barometer varies less in China than in Europe, seldom rising higher than 28 inches and 8 lines, or falling lower than 27 inches and 10 lines.

Diseases.

The climate of China appears to be highly salubrious, if a judgment may be formed from the small number of diseases, which seem to prevail among the inhabitants. They profess to be free from stone, gout, and gravel complaints; and are seldom affected with cutaneous disorders,—an exemption, which they ascribe to the use of tea. Epidemic fevers, however, are frequently generated in their crowded cities, and destroy great numbers of the lower classes. Many of the Chinese, also, are affected with a species of leprosy, which frequently occasions their fingers and toes to drop off; but it does not appear to be so highly infectious as the real leprosy; and no restriction is put upon those, who are labouring under the disease. It is conjectured to be merely the effects of an inveterate venereal lues spread through the system. The small-pox have prevailed in China for a considerable time; but, according to some, only since the tenth century, when they were introduced into the country by some Mahometan traders. Their physicians pretend to distinguish forty different kinds of small-pox; and when a favourable sort appears, they endeavour to propagate the disease from it, not by proper inoculation, *i. e.* by introducing the matter by incision; but by inserting into the nostril a little cotton wool dipped in the virus, or by putting on the clothes of the infected. But by the introduction of vaccination by Sir G. Staunton and Mr Pearson into Canton, and the progress which the practice is making throughout the empire, they have the prospect of being delivered from the ravages of that dreadful disorder more effectually, than by the most improved system of variolous inoculation. The venereal disease is not common in China, but chiefly exists in their sea ports, and is therefore called by the Chinese, the Canton ulcer. Even those, who are infested with the distemper, do not appear to suffer so much from its effects as persons in Europe; but generally find relief, and often a complete remedy, by the use of diluents and sudorifics. Sore eyes and total blindness are affirmed to prevail very generally, especially among the lower classes; and has been ascribed to a variety of causes; to their low, crowded, and smoky habitations; to the noxious effluvia from the dirt and offals, generally collected near the houses; to the custom of washing the face, even in the hottest days of summer, with warm water; to the uniform use of rice, or at least to the steams of the dishes filled with it and other stews; to the strong varnish used by those who work in japanning; to the smoke of their perfumed shops and candles morning and evening; to the practice of eating and drinking every thing extremely hot; to the blowing of the north winds over the snowy mountains of Tartary; and to the mode of inoculating for the small-pox, by inserting the virus into the nose. Osbeck, however, affirms, that the Chinese declared the greater part of the blind among them to have been born in that condition; and he himself denies, that they were so numerous, at least at Canton, as has been represented.

Soil. The general character of the soil is a loose sand, free from stones, of a reddish or yellowish colour, sometimes upon a bottom of clay, and furnishing, in certain places, a vegetative mould to the depth of five or six feet.

Earthquakes. Slight and short earthquakes are said to be frequently felt in all the provinces; but there is no appearance of volcanic productions in the country, though various substances of that description are found in some of the islands along the western and southern coasts.

Mineralogy. Several of the mountains contain mines of quicksilver, tin, copper, iron, silver, and gold; but it has been the general policy of the government to discourage the working of these ores. They are not, however, entirely neglected, and are all the property of the Emperor. The copper mines in the provinces of Yun-nan and Koeitcheoo are very productive; and the former yield a kind of white copper resembling silver, which is rendered softer and less brittle by being mixed with zinc or some similar metal. The Lolos procure, also, from the mines in Yunnan, both gold and silver in an impure state, which are well refined by the Chinese artists. Great part of the gold in China, however, is procured from the sand of the rivers and torrents, which flow from the western mountains, especially those of Setchuen and Yunnan. This gold is chiefly employed in gilding, and in making trinkets, and similar articles of merchandise. Iron, lead, and tin, are extremely abundant, and sold at a moderate price, in every quarter of the empire. Small rubies are also found in Yunnan, but the greater part of the precious stones, sold in this province, are supposed to be procured from the neighbouring kingdoms of Ava and Laos. In the western districts, lapis lazuli, resembling that of Europe, is found in sufficient abundance; and beautiful rock crystals, which are cut into buttons, seals, and other trinkets, are procured from the province of Fokien. There are numerous collieries throughout the empire, especially in the vicinity of Canton, which are worked by driving levels into the sides of the mountains; and the coal which they yield is immediately transported to the potteries in Kiang-see and Quan-tong. The coal is generally charred in large pits before being used, or pounded and mixed with earth, and formed into small bricks for heating the stoves used in cookery. In the same mountains, also, are very extensive stone quarries, from which are cut large blocks for sepulchral monuments, for the arches of bridges, for paving the streets, &c. These masses are cut by applying the saw to the upper surface, and working vertically to the depth required; and each stone is fashioned to the proper shape and size, before being removed from the parent bed. Between Canton and the first pagoda on the banks of the river, there is a succession of old quarries, which have been so regularly cut in this way, as to have the appearance of buildings in ruin. Marble quarries are not uncommon, particularly in Fokien; but the Chinese are said to be unacquainted with the best modes of working them. Sonorous stones, of which musical instruments are made, are found in the rivers and torrents, which flow along the bottom of the mountains in Yunnan, Koeitcheoo, and Shensee. They are of very different degrees of density and gravity; but the most esteemed is that called Yu, to which the Chinese authors ascribe a number of qualities, of which the modern specimens afford no proof. The most esteemed of these are of a whey colour, and the next in value are of the colours of bright blue, azure, indigo, citron-yellow, orange, logwood-red, pale-green, sea-green, deep-green, cinder-grey, &c. The largest of them, ever seen by the missionaries in the Imperial palaces, were two and a half or three feet in length, and one and a half in breadth. The best are so extremely hard, that, when cut and polished, the best tempered steel slides upon their surface, without making any impression; and so heavy, that four men, it is affirmed, could scarcely move a single block of two and a half feet in length, and half a foot in breadth. Another species, called the ox-fat-stone, resembling agate, is more common; but is inferior to the yu in hardness, weight, and tone, and is not found in pieces sufficiently large for making musical instruments. There is a third kind, resembling alabaster, which yields a hard metallic sound; and a fourth species, like marble, apparently vitrified in some parts, and seeming to be composed of talc and crystal. One of the Chinese musical stones, which was analysed by the Duke de Chaulnes, neither attracted the magnet, nor discovered any phosphoric quality, but shewed a number of small particles resembling pyrites; produced a strong effervescence when dissolved in acids; and yielded much the same results as black marble, several kinds of which have been found to be highly sonorous.

Mountains. The principal mountainous tracts in China are in the northern and western provinces. Many of those in the latter districts are cultivated, but those in the former direction are rocky and barren. In the provinces of Shensee and Ho-nan, towards the centre of the empire, and in those of Quantong and Fokien in the south, the mountains are generally covered with lofty forests, chiefly of pine trees, which supply excellent timber for ship building, and from which the emperor causes enormous trunks to be transported to great distances, to be employed in the construction of his palaces, and other public edifices. Those in the neighbourhood of Canton are remarkably wild and rugged; but those, which appear along the southern coast of the gulf of Pe-tche lee, which are nearly of the same size and form, and entirely detached from each other, are smooth regular cones, as if they had been fashioned by the the hand of art. Most of the mountains, which were observed by the gentlemen of the British embassy, were of primeval granite, a few of sandstone, and the smaller hills, of lime-stone or coarse gray marble. There is rather a curious mountain between the provinces of Quantong and Kiang-see, called Melin, to the top of which there is a paved road in a zig-zag direction; and at the top is a narrow pass cut through a granite rock, in the middle of which is a military post with two old pieces of cannon. The base of this hill is covered with cottages, and the view from its summit is said to present two very opposite prospects, one rich and beautiful towards the south, and another dreary and barren towards the northern regions. Of their mountains, the Chinese relate many wonderful stories; such as, that there are some of them, which render those who retire to live upon them immortal; that one in Shen-see is the exact figure of a large cock, and sometimes crows so loud, as to be heard at the distance of three leagues; that another in Fokien trembles before a storm, moving backwards and forwards like a tree agitated by the wind; that another in Shen-see vomits forth flames, rain, and wind, whenever any one beats a drum, or plays upon any musical instrument in its neighbourhood; and that one in Fokien represents a colossal figure of the god Fo, which is so immensely gigantic, that each of the eyes is several miles in circumference, and the nose several miles in extent.

Lakes.

Lakes and swamps are extremely numerous in China, and are supposed to cover nearly one-fourth part of the country. The principal lakes are two in Kiangnan, the Hong-tse and Kao-yeoo; the Tai-hoo, which is partly in the same province; the Tong-ting-hoo, in the province of Hoo-quang, said to be more than 80 leagues in circumference; and the Poyang-hoo in Kiang-see, which is subject to tempests like the sea, and, including the surrounding marshes, is nearly 100 leagues in length. It lies remarkably low, and is considered as the sink of China. Rivers flow into it in all directions, four of which are of a very considerable size; and the country around it has, for many miles, the appearance of a uniform marsh, without one visible sign of cultivation, and without any inhabitants but a few miserable fishermen, whose huts and boats appear here and there upon the brinks of the smaller pools. Its vicinity, in short, is described as one of the most desolate and dreary regions in nature; and, by such an extent of waters and swampy grounds, the temperature of the surrounding atmosphere is reduced a number of degrees below that of the adjacent country.

Rivers.

Hoangho, or Yellow River.

All the great rivers of China fall from the high lands of Tartary on the north of Thibet, and cross the plains of the country in their descent to the sea from west to east. The two principal rivers are the Hoangho, or *Yellow River*, so called from the yellow colour, imparted to its waters by the mud or clay, which it washes down from the mountains in the rainy seasons; takes its rise under the 35° of north latitude, in the mountains of Kokonor in Tartary; passes through a considerable part of that country along the outside of the Great Wall; enters China between the provinces of Shen-see and Shan-see; traverses the province of Honan, and a part of Kiangnan; and, after a course of 600 or 700 leagues, falls into the Eastern Sea, not far from the mouth of the Kiang. Its stream is extremely rapid, and frequently overflows its banks, along which in many places are raised dykes of great length, composed of alternate beds of clay and straw, while most of the cities in the vicinity of its channel are surrounded with strong ramparts of earth faced with turf. In these works immense sums of money have been expended; and the emperor Kang-hee declares in his last will, that 3,000,000 ounces of silver, or £1,000,000 sterling, were annually employed to restrain this river within its banks. But notwithstanding all these precautions, the low country through which it flows is so liable to inundations, that the Chinese affirm its overflowings to have been more destructive than the united effects of war, pestilence, and famine. Its breadth, at the distance of 25 leagues from its mouth, is not less than 500 or 600 toises; but its waters are so extremely shallow, that it is scarcely navigable to any extent. It washes down such an enormous mass of mud with its waters, that the quantity was found, by experiment, to equal two millions of solid feet in one hour; and this slimy matter, after entering the Yellow Sea, being carried by a strong wind to the Gulf of Pe-tche-lee, where the stillness of the water allows it to subside, forms innumerable islands and sand-banks in that remarkably shallow bay.

Yang-tse-Kiang, or Son of the Sea.

The next great river of China, is the Yang-tse-kiang, or *Son of the Sea*, which has its source in the country of the Too-fan, about 33° of north latitude; traverses a part of the provinces of Yan-nan, Se-tchuen, Hoo quang, and Kiang-nan, through a course of more than 700 leagues; and falls into the Eastern sea in the 32° of north latitude, opposite to the island of Tson-ming, which is supposed to have been formed by the soil carried down by the stream, and which is not less than 20 leagues in length by six in breadth. This river is less rapid, but much deeper than the Hoang-ho. At the distance of 30 leagues from its mouth, it is fully a league in breadth; and, at the distance of 140, it is not less than half a league wide. It forms numerous islands in its course, which it is continually sweeping away, and replacing with others; and, from the reeds which grow upon these accumulations of soil, to the height of ten or twelve feet, the cities along its banks are abundantly provided with fuel. In consequence of these shifting banks, and the great rapidity of its stream, its navigation is very dangerous, and daily proves fatal to numbers of vessels.

Smaller rivers.

Some of the smaller rivers are, the Pei-ho, which flows through the province of Pe-tche-lee, and which has remarkably low, sandy banks; the Eu-ho, or *precious river*, called also Yung-leang-ho, *the river upon which grain is transported*, flows from the westward, and forms a confluence with the Pei-ho at Tien-seng; the Pei-kiang-ho, which rises in the mountain of Melin between the provinces of Kian-see and Quan-tong, flows by the port of Canton, and is familiarly known in Europe by the name of *Bocca Tigris;* and the Kan-kiang-ho, in the province of Kiang-see, in the course of which is a remarkable cataract called Shee-pa-tan, or the *eighteen cataracts*, a succession of torrents formed by ledges of rock running across the bed of the river. It is a place greatly dreaded by the Chinese, on account of the multitude of boats which are dashed to pieces in the passage; and yet it is represented as by no means so dangerous as the fall at London bridge, about the time of half tide. But the Chinese display neither dexterity nor courage in the management of their vessels in such situations of danger; and, instead of exerting their own attention and activity, are apt to leave the boat to itself, while they set to the burning of sandal wood matches, and the sounding of their gongs, to appease the river-deity. The country around this cataract is described as peculiarly beautiful, the stream itself transparent, and abounding in fish, its bold rocky banks fringed with wood, and the mountains covered with the larch fir, and a fine plant called *camelia Japonica*, resembling the tea shrub.

China produces the greater part of the fruits, which

Vegetable productions.

Fruits.

are known in Europe, with several others peculiar to itself; but, except the practice of ingrafting, they employ few artificial means for improving the quality of their fruits, and suffer them to grow almost in a wild state. Hence, except the grapes and pomegranates, the fruits of China are very inferior in flavour to those of European growth. Their *apples* are soft and spongy; their *pears* of an immense size, † sometimes excellent, but commonly of a remarkably austere taste; their *cherries*, universally indifferent; but their *peaches* generally good, especially one kind of a flat shape. They have various kinds of *apricots*, which are in general detestable; but one kind, which grows wild on the waste soils and most unfavourable situations, yields, from its kernels, an excellent oil for lamps, while the stones are employed as fuel in the small stoves. Apricots are frequently preserved both in a dry and liquid state, and sometimes the juice only is pressed out, boiled into a pretty thick consistency, and formed into a kind of lozenges, which may be kept for any length of time, and which, when dissolved in water, make a very cooling and refreshing beverage. *Grapes* are very abundant, but it is said that the government prohibits the making of wine; but the fact is, that the Chinese grape is not capable of producing it; and it was with great difficulty, that the missionaries at Pekin succeeded in their experiments for that purpose. The *olives* are of different kinds, but none of them seem to be cultivated for the purpose of making oil. It is affirmed, that, before gathering the fruit, a hole is bored in the trunk of the tree, filled with salt, and closely covered up, and that, at the end of a few days, after this operation, the olives drop off. *Oranges* are found in great variety in China, but the most esteemed is of a small size, smooth soft skin, and a reddish yellow colour. Another kind, of a large size, is of a firmer texture, not easily peeled, nor capable of having the pulp divided into separate parts; but is of a wholesome quality, and, after being softened at the fire and mixed with sugar, is frequently given to the sick. *Lemons* and *citrons* are also common, some of which are large like the shaddock; and a smaller kind, resembling a walnut, is cultivated with particular attention for culinary uses. There are not wanting mangoes, bananas, pine-apples, tamarinds, figs, almonds, and other fruits sufficiently known; and there are many again peculiar to the country, of which the most celebrated are,—the Lee-tchee, resembling a date, which the Chinese frequently dry in the rind, using it in their tea, to which it communicates a slight acid taste, and which the missionaries have represented as a most delicious fruit, but which is said to have the taste of an insipid onion, and to be of a very heating nature, covering the skin with pustules, when eaten to excess.—The Long-yan, or dragon's eye, which has a tart juicy taste like the last mentioned, but more agreeable and wholesome, at least to Europeans.—The Hoang-pee, which has a sourish taste, like that of gooseberries, when scarcely ripe.—The Tcheetse, which resembles a fig, about the size of an ordinary apple, and which, when dried and flattened, are called Tchee-ping, and are then equal to the best figs of Europe.—The Lin-kio, a species of water chesnut, of a cooling and agreeable taste, sometimes sold like filberts, in a green state, sometimes dried, powdered, and made into soup, and sometimes baked in the oven with sugar and honey. In order to propagate the plant, it is sufficient to throw the seeds, about the end of autumn, into the shallowest places of ponds or rivers, in a south exposure.—The Pee-tsee, another water chesnut, which grows only in the southern provinces, wholesome and cooling, and much used by the sick. Its leaves are long like those of the bulrush, and hollow like the stalk of the onion. Its fruit is found in a capsule formed by the root, in which it is inclosed, like a chesnut within its husk, and from which it may be extracted without injuring the plant.—Belvidere, or Chenopodium, found chiefly in a wild state, the leaves of which, resembling those of flax, are eaten as sallad with salt and vinegar, or baked with meat, to which they communicate an agreeable flavour; its principal stalk and root are also dried and baked; sometimes reduced to a kind of flour, which is made into small loaves, and used by the poorer classes in seasons of scarcity.—Hemp is often cultivated in the Chinese gardens, not for the purpose of being manufactured into cloth; but for the sake of its leaves and seeds, which are mixed with tobacco for smoking.

Pot-herbs.

Pe-tsai.

Lien-hoa, or water lily.

In their gardens are tobacco, sallads, leeks, onions, garlic, spinage, carrots, turnips, raddishes, celery, mustard, beans, calavances, pepper, ginger, pumpkins, cucumbers, gourds, musk, and water-melons, and many of the common European pot-herbs, of which they procured the seeds from the Portuguese. But their most common pot-herb is the Pe-tsai, or white herb, a kind of brassica or cale, which the Chinese prefer to all other vegetables, and with which large fields are often covered. It grows to the height of two feet; and a single plant will often weigh from ten to fifteen pounds. It has an insipid taste, not unlike to that of cos-lettuce. It is sometimes half-boiled and dried, or salted in brine, and prepared something in the manner of the sour krout of the Germans. But one of the most abundant, most curious, and most generally useful of these plants is the Lien-hoa or Lien-wha, the water lily of China, formerly known to botanists under the name of *Nymphæa Nebumbo*, but now considered as a new genus, and distinguished by the appellation of *Nelumbium*. The leaves are round, broad, and large, thick and fibrous, and indented towards the middle; some of them floating on the surface of the water, and others rising upon long stems. The root, which is sometimes 12 or 15 feet in length, and of the thickness of a man's arm, of a pale yellow colour internally, but milk white in its external surface, creeps along the bottom of the lakes, attaching itself to the mud or earth, by a multitude of small filaments. The flowers are composed of several petals, disposed in such a manner, as to resemble large tulips when half blown; and from the middle of the flower rises a conical pistil, round and spongy, divided into cells, which are filled with oblong seeds, covered with a husk like the acorn, and composed of two white lobes. It grows spontaneously in almost every lake and morass, from the middle of Tartary in the north, to the province of Canton in the south; and yet it is with the utmost difficulty, that it can be preserved by artificial means in Europe, in places where the climate is neither so cold nor so warm as many parts of China, where it vegetates naturally and luxuriantly. It is said to form one of the ingredients, which compose their liquor of immortality, and has been celebrated by their poets of every period, as an emblem of creative power. The leaves of the succeeding plant are found involved in the middle of the seed, in a perfect state, and of a beautiful green colour. The large leaves, also, which spread themselves over the surface of the water, fold themselves together like an umbrella, at the setting of the sun, and gradually open again at his rising. These circumstances, conjoined with the general opinion among Oriental nations, that water was the primary element, and the first medium of creative influence, have naturally recommended this singular, useful, and beautiful plant to their imaginations, as the most expressive symbol of that influence. There are various kinds of the Lien-hoa, which are distinguished chiefly by the colour of the flower, the red and white, rose-coloured with single and with double flowers, pale red striped with white, and yellow, which is very rare, and which is supposed to be the same as the nymphæa of Europe. It requires no culture, and may be propagated either by seed, or more speedily by the root. Though it grows naturally in water, yet it can endure a considerable degree of drought; and, though rather fond of heat, yet produces the largest flowers in the northern provinces. Its seeds are eaten in China, as filberts are in Europe, and are reckoned most delicate when green, though more indigestible in that state. They are preserved also with sugar in a variety of ways. The root likewise forms an article of food, sometimes pickled with salt and vinegar, and eaten along with rice; sometimes powdered, and made into soup, with water and milk; and is said to be extremely wholesome in every mode in which it is prepared. Its leaves are employed in wrapping up fish, fruits, salted provisions, &c.; and, when dry, are sometimes mixed with tobacco, to render it softer and milder in smoking. In order to afford an example to the people in raising so valuable a vegetable, the government has commanded it to be cultivated in all the lakes, marshes, and waste grounds belonging to the state; and even the ditches, which surround the emperor's palace, as well as the canals in his gardens, are planted full of it. It covers entirely those immense sheets of water, which are in the centre of the city of Pekin; and when its leaves are green, and flowers in bloom, it forms one of the most beautiful objects in that capital.

---

† One of them, measured by M. De Guignes, was about five inches in height, four in diameter, and thirteen and a half in circumference.

Flowers and flowering shrubs.

In the gardens, around the cottages of the Chinese, were observed beautiful asters and balsams, holly hocks, malva, amaranthus, and the nerium oleander, sometimes called the Ceylon rose. Around the lake See-hoo, the most prevailing flowers and shrubs, noticed also by Mr Barrow, were the hibiscus, lilac, mulberry, mimosa, rhamnus, sambucus, rose, juniper, cotton plant, amaranthus, xeranthium, epidendrum, flos acris, which vegetates without earth or water, celesia or cockscomb, jasmine, myrtle, rosa sinica, tuberose, China pink, sweet basil, sweet-scented olive, peony of various hues, and a species of magnolia, of which the flowers appear before the leaves. Some of the more remarkable flowering shrubs, peculiar to the country are,—the oo-tong-tchu, resembling a sycamore with large leaves, upon a stalk about a foot in length, extremely bushy, and so loaded with flowers as completely to exclude the rays of the sun.—The mo-lien, which has a few slender branches, covered with red bark, studded with small white spots, with a small number of large broad leaves at the lower extremity; and which bears in the month of December large flowers of seven or eight sharp-pointed petals with long filaments at their extremities, all the leaves dropping off when the flower begins to blow.—The la-moe, resembling the laurel of Europe, and also bearing flowers in winter of a yellow colour, and an agreeable smell like that of the rose.—The tcha-hoa, resembling the Spanish laurel in its wood and foliage, of which the leaves do not drop in winter, and the flowers of which appearing in December, of a fine rose colour, adhere without any pedicle close to the branches.—The yu-lan, one of the most beautiful ornaments of the Chinese gardens, which rises to the height of a tree, and when in flower, resembles a cropped walnut bush with its branches stuck full of lilies; but its flowers, which perfume the air to a great distance, remain only for a few days.—The autumnal hai-tang, originally brought from the rocks on the Chinese coast, celebrated by their poets as the rose or lily by those of Europe, and the flowers and foliage of which are very generally imitated by their painters and embroiderers in ornamenting their works, has branches of a fine purple hue, covered with prickles of a deep green colour, bears its flowers in clusters at the extremity of its branches, which resemble the blossom of the peach tree, and which shoot out anew, as the old petals drop off.—The moo-tan, or peony shrub, called also the king of flowers, an object of great attention among the florists of China, who vie with each other in producing the finest specimens, and sending the best to the Emperor, is a large shrub like the orange tree, and bears a showy sweet-smelling flower, like a rose, of a beautiful gold colour.—The pe-ge-hong, or "red of a hundred days," so named from the duration of the flower, the calyx of which is red on the outside, or a pale yellow within, containing six crimson coloured petals, each supported by a slender whitish stalk: these flowers, growing in bunches at the extremity of the branches, succeed each other, if properly shaded, for the space of three months.—The ye-hiang-hoa, or "flower which smells in the night," has weak slender branches, requiring to be supported by bamboo reeds or hoops, and bears a greenish yellow flower, which emits an exquisite perfume during the night. It is highly valued by the Chinese, who purchase the finest plants sometimes at the rate of 30 taels (about L. 10); but it thrives only in the southern provinces, and can be preserved at Pekin only in hot-houses.—The kiu-hoa, or parthenium, which the Chinese florists have brought to great perfection, both as to beauty and odour, and of which they are said to enumerate more than 300 species, propagating it by seeds, suckers, grafts, or slips, and sometimes producing varieties, by joining together two slips of different colours, tying them closely with pack-thread, after cutting a notch in each nearly to the pith.

Medicinal plants.

The medicinal plants produced in China are represented as extremly numerous and valuable. The most remarkable are rhubarb, the best of which grows in Se-tchuen, and of which those roots which are heaviest and most variegated with veins of different colours, are most preferred.—Hiao-tsao-tong-kong, or "herb in summer becoming worm in winter," which is a rare plant, supposed to be originally from Thibet, resembling ginseng in its properties as a stomachic and general tonic, and from its soft substance and yellow colour, remarkably like a caterpillar worm in its appearance.—San-tsee, that is, "three and seven," so named from having three leaves at the extremity of its middle and highest stem, while there is only one at the end of the other seven stems, and the root of which is accounted a sovereign remedy in the small-pox; and as a species of grey goat is fond of browsing on its leaves, the Chinese physicians have supposed the blood of these animals to possess the same properties as the herb itself.—Cassia-tree, which is found chiefly in the western parts of Yunnan, and which bears long pods resembling a hollow pipe divided into several cells, and containing a pulpy substance similar in taste to the cassia used in Europe.—Foo-lin, supposed to be a kind of mushroom, growing always in the vicinity of pines, several feet beneath the surface of the earth, attached to their roots like a fungus, and of which as

Ginseng.

experienced Chinese botanist is said to be able to discover the precise situation by the smell which it exhales. It is said to admit of being transplanted; and its inner part is used as a remedy in diseases of the liver, chest, &c. but it is said to be necessary for the patient to abstain from acids while using it.—Artemisia, or mugwort, called in China the physicians' herb, is used for a variety of purposes. It is kept in flower-pots as an ornamental plant, and continues long in flower. Its leaves, when powdered, are taken as a styptic in cases of bleeding at the nose, or in spitting of blood. The leaves of the prickly mugwort are often dried and used as tinder, or as stuffing in making mattresses, quilting, &c. This is chiefly the use made of the wild mugwort, the leaves of which are more soft and silky, and the downy balls of which are formed into girdles for the sciatica, or quilted stockings for rheumatism in the limbs.—Tchoang, a name given to the large comfrey, the root of which is taken by the wealthy Chinese in pills, or in decoction, every morning, as a salutary medicine in general.—Ginseng, called by the Tartars Orhota, that is, "the queen of plants," is the most esteemed of all the Chinese medicinal plants; and, in their opinion, is possessed of almost every possible property. It abounds in the mountains of Eastern Tartary, in places where the trees are tall, and the ground free from underwood, and forms the principal wealth of that country. No private person, however, is allowed to gather it, but the Emperor sends yearly ten thousand soldiers for the purpose of collecting it; a service apparently rather unwarlike, but yet neither exempt from danger nor fatigue. They are loaded with their provisions, consisting of toasted millet; have neither beds nor tents; but pass the night in the forests or at the foot of a rock, exposed to all the inclemencies of the weather, for the space of six months. A certain extent of forest is allotted to every hundred, and these again are stationed at certain intervals in bands of ten men, and then advance in a regular line, searching carefully for the plant as they proceed. After the time, appointed for traversing a given space, is expired, the mandarins, who preside over the work, and who reside in tents in the neighbourhood, send messengers to see that the number of troops be complete, to search for such as may have lost their way, to fill up the places of those who have perished by wild beasts, and to appoint another portion of ground for them to pass over. Ginseng, besides being employed in almost every disease by those who can procure it, is regarded as a general cause of longevity, and is therefore used by such as are in good health, as a mean of increasing and preserving their vigour. The Jesuit Lafitau, guided by the description given of the Chinese ginseng by Jartoux in *Lettres Edifiantes*, discovered the same plant in the woods of Canada, in 1745; and, according to his account, the Indian name, *Garent-oguen*, has a similar signification as the Chinese word ginseng. Both of them signify a man's thigh, an appellation which has been given to the plant, because its roots are often found to resemble the body of a man from the middle downwards; and hence it has been supposed by some botanists to be the same with the Mandrogora of the ancients.—A celebrated drug among the Chinese, called Ngo-kia, may be here mentioned, though it is not indeed a vegetable, but merely a kind of glue made from the skin of a black ass, after it has been steeped in the water of a particular well near the city Ngo-hien, in the province of Shan-tong. It is supposed to be useful in various distempers, but chiefly, according to the report of the missionaries, in diseases of the lungs.

Trees.

Throughout the vast extent of the Chinese empire, is found every kind of tree known in Europe; and a multitude of others peculiar to the country.* The most useful and singular are:—The Tie-lee-moo, or iron wood, which grows to the height of the oak, and the wood of which is remarkably hard, and so heavy as to sink in water; whence it is generally used by the Chinese in making anchors.—The Nan-moo, or Chinese cedar, one of the tallest trees and most durable kinds of wood in the country, which is much used in making the beams and pillars of the Imperial Palaces.—The Lo-ya-song, a species of pine, resembling that of Europe, but distinguished by several peculiarities, such as, that its leaves fall in autumn, that its wood is exceedingly hard, and that its sap is of a poisonous nature, occasioning pimples and blisters on the skin of the workmen in cutting it.—The Siang, resembling a chesnut, especially in its fruit, the external husk of which is employed as a substitute for the gall-nut in dyeing, and the kernel given to the hogs, though sometimes boiled in water and vinegar, and used by the mountaineers as food.—The Lung-ju-shu, about the size of a plum-tree, the wood of which is employed in making furniture, and the fruit of which, resembling unripe cherries, yields a kind of jelly, with which the country people rub their hands in winter, as a preservative from chilblains.—The Tcha-ke, said to be without bark, to burn readily even when green, to last longer than any other fire-wood, and, when made into charcoal, to produce a strong heat without either smoke or smell.—Tchoo-koo, a kind of sycamore, resembling the mulberry in its appearance, but the fig-tree in its fruit, and the inner bark of which is used in the manufacture of paper.—The Kin kooang-tsee, or sour jujube, a large tree, with fine-grained wood, and fruit resembling large jujubes, the stone of which is shaped like a heart, and formerly much used as a superstitious ornament.—The Tse-sing-yuen-pe, or juniper cypress, resembling the juniper in its wood and the cypress in its leaves, with a round green berry, larger than that of the juniper, containing two reddish grains shaped like a heart, and extremely hard.—The Oo-kieoo-moo, or tallow-tree, about the size of a cherry tree, with leaves of a bright red colour, shaped like a heart, the seed or fruit of which is surrounded by a pulp resembling tallow in colour, smell, and most of its properties, which, after being mixed with a little linseed oil, is made into candles, but from its not being sufficiently purified, they generally burn with a thick smoke, faint light, and unpleasant smell.—The Wax-tree, of which there are two kinds, one short and shrubby, growing in dry rocky ground, and the other taller, requiring a moist soil. On these trees, a kind of white wax is deposited by certain small insects, which do not naturally frequent them, but which, when once placed upon them, always remain. The wax, which is gathered in September, is white, bright, and transparent; and a single ounce of it, mixed with a pound of oil, is said to produce a substance little inferior to bees-wax. It is much used as a salve; and is also taken by the Chinese, in a dose of one ounce, as a stimulant or exhilarant, when they have occasion to make any public appearance, which requires courage and assurance.—Tong-tchoo, resembling the walnut, when covered with its fruit, from the kernels of which is pressed a peculiar oil, which burns well, though with much smoke in its natural state; but which, when duly prepared, is known by the name of Meng-yeoo, or oil of wood, much used by the Chinese as a paint or varnish.—The Tchoo-tchoo, or varnish-tree, resembling a small ash, and bearing neither flowers nor fruit, yields from incisions made in its trunk, a reddish gum, of a very acrid nature, of which is prepared the celebrated varnish used by the Chinese. It is so valuable, that the proprietors of these trees are said to let them to merchants for the season, at the rate of three pence per foot; but so very corrosive and poisonous, that the workmen, who collect it, are obliged to cover their faces and hands, and also to rub themselves with a preparation of rape oil, as a security against its malignant vapour, which, without such precautions, is said to generate a disease resembling the leprosy. A pound of this varnish is supposed to cost the merchant at least 1s. and 8d. sterling; but is highly valued by the workers in varnish, as it not only communicates a beautiful transparent gloss to the wood upon which it is laid, but also preserves it effectually from damp and worms.—The Tse-tan, or rose wood, is of a blackish red colour, beautifully striped and variegated; is remarkably heavy, and of an agreeable smell; and is made into various articles of furniture, which are sold at higher prices than the finest varnished work.—The Tchang, or camphor tree, which grows to a large size, and the wood of which has a very penetrating smell, which prevents it from being attacked by worms. The camphor is procured by cutting the young shoots into small pieces, steeping, boiling, and straining; and it is purified by being exposed in a copper bason to a moderate heat, between layers of a finely pounded old earth.

---

* The Chinese gardeners have a wonderful passion for reducing their flowering shrubs, and even their forest trees, to a dwarfish size; and the missionaries assure us, that they have seen cedars and pines, which were more than 40 years old, and yet not above two feet in height, while the trunks, branches, and leaves, were all well-proportioned.

Bamboo.

—The bamboo, a reed which grows to the height of a tree, of 20, 30, and 40 feet, abounding in every part of China, but particularly in the province of Tche-kiang, where large forests of it are found. Its trunk is hollow, and divided by knots, but is capable of sustaining a considerable weight. It is applied in China to a greater variety of purposes, than any other substance whatever. Its young shoots are used as food, and its fibres as wicks of candles. Its hollow stems are employed as pipes in conveying water, or are split into thin threads, and woven into matting or cables. Its wood is bruised and made into paper, or in its more solid state is employed in making all kinds of furniture and utensils, trunks, chairs, tables, bedsteads, wheel-barrows, carts, fences, water-wheels, &c.—The Koo-tchoo, resembling the fig-tree, and yielding a milky juice used by the Chinese in laying on gold leaf in gilding.—The Tong tsao, a species of cane or bamboo, resembling the elder of Europe, the pith of which is carefully dried, rolled, and sliced into thin pieces for the use of the painters of artificial flowers, fruits, and insects.—The Betel, which grows like ivy around the trunks of trees, the leaves of which, mixed with the areca-nut, the Chinese chew almost continually, presenting it to each other as Europeans do their snuff or tobacco, and which they consider as strengthening the gums, preventing bile, and relieving asthma.—The cotton-tree is cultivated successfully in the southern provinces; and generally sown after the grain is reaped.—The mulberry-tree, which attains in some provinces, a greater height than in others, but seems to thrive in every soil, is chiefly cultivated for the sake of its leaves in rearing the silk-worm, but its fruit also is eaten by the Chinese.

Sugar-cane

—The sugar-cane, which grows in China to the height of six or seven feet, with the knots at a distance of six or seven inches, is cultivated chiefly in the southern provinces, and planted much in the same manner as in the West Indies. The juice of the cane is expressed by temporary mills erected on the plantations, consisting of a pair of cylinders, sometimes of stone, but generally of hard wood, placed vertically, and put in motion by oxen or buffaloes. From the bottom of these rollers the expressed juice is conveyed by a tube carried under the floor, into a boiler which is sunk in the ground at one end of the apartment, where it is boiled to a proper consistency. The Chinese are not acquainted with the mode of refining sugar; but they procure from the cooling syrup a very fine kind of sugarcandy, which is sold at Canton in a pulverized state, as white as the finest refined sugar in Britain. The molasses are used chiefly in preserving fruits, and particularly in making a conserve of the roots of ginger, of which the Chinese are remarkably fond. Sometimes they are distilled along with fermented rice, in the preparation of a kind of burnt wine, already mentioned.

Tea.

—The Tcha, Tha, or Tea-tree, grows equally in the mountainous and level districts; but it prefers a light and rocky soil. It is sown in March, by putting seven or eight seeds into one hole, of which often only one or two spring up. The young plants are afterwards transplanted in rows, and in spaces of three or four feet around each of them. They yield crops of leaves three years after being sown, but they require to be renewed every five or six years, as the leaves then begin to grow hard and harsh. The appearance of the tea-shrub resembles that of a myrtle, its root that of the pear-tree, and its flowers those of the wild white rose. On the more tender branches grow small soft berries of a green colour, filled with yellow grains, and on the other branches pods of a larger size and of different shapes, some round, containing one pea, and others long, containing two or three. There are different modes of cultivating the tea-plant in different provinces. In Kiang-nan it is not allowed to grow higher than six or seven feet; but in other places, to the height of ten or twelve. In the southern provinces, when not cultivated for the sake of its leaves, it is frequently planted in hedge-rows. The leaves are gathered at the beginning, the middle, and the end of spring; and their colour is different, according to the time of gathering. At the beginning of the spring, they are of a bright green, of a livid green about the middle, and of a dark green at the end of the season. The new leaves from the young plants are accounted of the first quality; those which push out immediately after these, of the second; and those which appear last, of the third. The leaves from the extremities of the branches, and from the higher parts of the shrub, are the most tender, those from the middle of the bush are less so, and those from the lower parts are more coarse. After the leaves are collected, they are exposed to the steam of boiling water. They are then made to shrivel or roll together, by being placed on plates of copper, of iron, or of baked earth, held over the fire, and are next dried thoroughly by exposure to the sun. The green teas, however, are not exposed to the sun's rays, which are said to make their colour black; and in the preparation of some of the finer sorts, especially that which is called Tchu-tcha, every leaf is rolled singly in the hand with great care.* The Chinese give the name of Tcha, however, to several vegetable productions, which are not really tea; and among other substances, a species of moss particularly, which grows upon the rocks in the province of Shang-tong, is often mixed with genuine tea, and sold in its stead even in China.

---

* Mr Osbeck affirms, that, in the course of preparation, the tea passes through many dirty hands; and that particularly in packing it in the chests, it is trodden firm by the naked, and sometimes bleeding, feet of a Chinese porter, in a state of profuse perspiration.

The different kinds of tea.

There are, in fact, only two kinds of tea, the green and the black; and all the rest are either mere combinations of these two in different proportions, or are simple varieties produced by difference of soil, of culture, and of gathering.

Black tea.

The black teas are generally brought from the province of Fo-kien. Of those the most common is the bouy, or rather vouy, as the Chinese pronounce it, or bohea, as it is more generally called. It takes its name from a celebrated mountain in the province of Fo-kien, called Vouy, which is covered with pleasure-houses, temples, and hermitages of the Bonzes. When of a good quality, this tea should have a colour of a black cast, leaves of a moderate size, a little rounded in their shape, and a little reddish in their hue. If it resists, and as it were pricks the hand upon being touched, it is a proof of its being well dried; but if it breaks, and crumbles into powder, it is then too old, or too much roasted. The water, in which it is infused, should have a deep yellow colour, and a taste not over austere. It is more esteemed by the Chinese than the green tea, and is accounted lighter, sweeter, and a better stomachic. It is sold from 12 to 15 taels per pic.—The congo, or rather cong-foo, is only a finer kind of bohea; and its infusion is of a lighter colour, inclining to green. Its odour, however, is seldom so agreeable. It costs from 25 to 27 taels per pic.—The saotchong, or sushong, is one of the finest kinds of black tea; and its leaves, after being unfolded in the water, should be free from spots. It communicates a delicate greenish tinge to the water, in which it is infused, and has a very agreeable odour. It is sold from 40 to 50 taels per pic.—The pekao is the mildest sort of black tea, and said to be the least heating in its effects. It gives a light greenish tinge to the water, and has a sweet violet smell. It is sold from 34 to 60 taels per pic. There are also other black teas, named campouy, pao-tchong, and ankay, the last of which is a coarse tea from Kiangnan, which is seldom exported to Europe.—The Padre sushong, or the Poo-eul-tcha, so called from a village of that name in the province of Kiang-nan, is gathered from tea plants, which are allowed to attain their greatest natural size, and which are very tall and bushy. The leaves of this tea are long and thick, not shrivelled like the other teas, but packed up in masses like tobacco, and sold at a high price. It gives a reddish tinge to the water, and has less flavour than other kinds. Osbeck calls it the best tea that can be drunk, while De Guignes speaks of it as having a sweetish taste, and in no respect agreeable. It is employed chiefly, he adds, as a remedy in colics and diarrhœas, and has the effect of stimulating the appetite.—The mao-tcha, or imperial tea, sometimes called bing, which is reserved chiefly for the use of the Emperor, is composed of the tender leaves, which are collected from the young plants of the bohea. Its leaves are large, and of a beautiful green colour. It communicates a green tinge to the water, and has a slight smell of soap.

Green tea.

The green teas are produced chiefly in the province of Kiang-nan; and are conjectured by Osbeck to be naturally the same as the black; but to derive their peculiar colour either from repeated dryings, or from being exposed to the heat upon plates of copper, while the other are laid upon plates of iron;—a proof of which he finds in the circumstance of green tea having a tendency to occasion purging, while the black has rather an opposite effect. The principal green teas, are the Songlo, which is so named from a mountain in Kiang-nan, under the 30° of north latitude, which is covered with tea shrubs. Its leaves are longer and more pointed than those of the black tea, and they ought to be of a bright colour without spots. It is of an inferior quality when its leaves are yellow, or its smell like that of pilchards. Its appearance should be livid, and its infusion green. It is considered as of a corrosive nature; and is sold from 24 to 26 taels per pic.—The hay-suen, or hyson, which, when of a good quality, is of a livid colour, tinging the water with a lively green. Its leaves are bright without spots, and entirely unrolled after infusion. It has a slight odour of roasted chesnuts; is considered as very heady; and is sold from 50 to 60 taels per pic.—The tchu-tcha, which is rolled up with the hand in a round form like a pea, and a smaller kind of which is that called *gunpowder tea*, is sold from 65 to 70 taels per pic. There are other green teas, the Tonkay, the Hay-suen-skin, the Shulan, and several sorts, which are little known even at Canton; but in these distinctions, says De Guignes, there prevails no small degree of quackery. There is a kind called Kael-tcha, which is merely the refuse of all the other kinds mixed together, and which is chiefly sold to the Mogul Tartars, a people who, from eating great quantities of raw flesh, are much afflicted with indigestion, when they do not make use of tea; and who, in regard to that article, are not remarkably delicate in their taste.

Mode of proving, Preserving, And using tea.

The manner of proving the finer teas, is to put a small quantity into a cup, to pour on it pure spring water at the full boiling heat, to place the saucer above the cup, filling it also with boiling water to increase the heat, and, after a sufficient time has elapsed for the leaves to unfold themselves, to examine their appearance, and the colour of the infusion. In China, the common tea is preserved in narrow-mouthed earthen vessels, but the finer sorts are inclosed in porcelain vessels, lead or tin canisters, covered with fine bamboo matting; and the people, both of that country and of Japan, generally keep their tea till it be a year old before using, as they conceive it to possess too much of a narcotic quality when new. In using tea, the Chinese generally pour boiling water on it as is done in Europe, and drink it without milk or sugar; but in many places, both in China and Japan, the tea is reduced to a fine powder, and placed in a vessel upon the table, the cups are filled with boiling water, a tea-spoon full of the powder thrown into each cup is then stirred about till the liquor begin to foam, when it is drunk off while quite warm. A general rule among the Chinese also, is not to drink tea when fasting, as it is then more ready to affect the nerves, and to create giddiness, especially in persons of a spare habit of body.

Attempts to introduce the tea shrub into Europe.

The tea shrub is cultivated only in China and Japan, and is supposed to be indigenous to one or both of these countries. The attempts to introduce the plant into Europe have repeatedly failed, chiefly it is supposed from the bad state of the seeds. It is recommended by those, who have resided in China, to procure the seeds fresh, ripe, and white; to inclose them in wax after having dried them well in the sun, or to shut them up in their husks in a box made of tin, or rather to sow fresh seeds in boxes of fine light earth immediately upon leaving Canton, covering them with wire to keep off rats and other vermin; to preserve them carefully from the sea-dew; to water them gently now and then with fresh or with rain water; and, when the shoots begin to appear, to shelter them from the sun, and keep them slightly moist. But it may be questioned whether the tea plant could be cultivated, and the tea prepared in any European country,* where the price of labour is so high, at a much lower rate than it is brought from China. The cultivators of it in that country are said to sell the very best to their own merchants from 4d. to 2s. per pound, who again dispose of it to the East India Company at the rate of 8d. per pound for the ordinary kinds, and 2s. 8d. for the finest parcels.†

Animals. Wild. Game.

In China, there are few animals which are not to be found in other countries of the East, though, in such an extensive empire, there may naturally be supposed to be numerous diversities in the appearance even of the common tribes. Wild animals of every species, except the lion, which is unknown in China, abound in the mountains and forests; the elephant, rhinoceros, leopard, tyger, wolf, bear, buffalo, camel, dromedary, horse, ape, &c. Some of the *camels* are not higher than horses, and have two bunches on their shoulders. A species of *tyger* without a tail, and with a body resembling that of a dog, is described as remarkably swift and fierce; and the Chinese affirm, that when a traveller escapes his fury by ascending a tree, the creature stations himself at the root of the tree, and, by uttering loud yells, brings to the spot all of the same species within hearing, who, by their united endeavours, dig up the tree by the roots, and devour their miserable victim. The Chinese hunters are said to destroy this animal, by forming a circle of strong palisades, within which they take their stand, and attract the tygers to the spot by imitating their cry, and then dispatch them with their arrows while attempting to dig up the stakes. There are various kinds of *apes*, one species of which named sin-sin, but suspected to be altogether a fabulous animal, is described as equal in size to an ordinary man, and as imitating very nearly the motions of human beings. A species of *flying fox* is also said to be found in the frontiers of Northern Tartary, which, by means of a thin membrane extending on each side from his fore to his hind leg, is able to dart from one tree to another, but always from a higher to a lower situation. A rat as large as an elephant, a tyger resembling a horse covered with scales, griffins, dragons, and other chimeras, some of which are described in a printed collection of observations by the emperor Kang-hee, furnish sufficient proof of the deficiency of the Chinese philosophers in the department of natural history. Those wild animals denominated game are said to be remarkably abundant; stags, deer, goats, elks, hares, rabbits, squirrels, &c. A kind of *stag*, not much larger than a middle-sized dog, is described as one of the most beautiful quadrupeds in China, and is bought by the mandarins, to be kept as curiosities in their gardens. The *musk deer* is very common in all the provinces, is nearly of a black colour, and without horns, and its flesh is frequently used at the most luxurious tables. The musk is found only in the male in a thin membranous bag, covered with a fine soft hair. Some of the missionaries affirm, that the ordinary food of this animal is the flesh of serpents, which it easily procures by stupifying them with the odour of its musk; and that the Chinese peasants knowing this fact, secure themselves from these reptiles, by carrying always a few grains of musk about their persons.

Domestic animals.

The domestic animals in China are less numerous, than the extent of the empire and number of inhabitants might afford reason to expect. Few are employed in the labours of agriculture, and still fewer are reared for the use of the table. The *horse* in China has neither the strength, beauty, nor swiftness of the European breed. Some of the emperor's stud are not deficient in size and spirit; but no means are used to improve the breed. The Chinese horses in general are not provided with shoes, so that their hoofs are soon destroyed, and, in six years, the best of them are rendered totally unserviceable. A Scotch poney, in short, wild from the mountains, and untouched by the comb, is affirmed to be equal in appearance and usefulness to any of the cavalry in the Chinese emperor's service. Asses, mules, and buffaloes, are more numerous than the horses, and are chiefly used in the labours of agriculture. The *mules*, as formerly mentioned, are preferred even to the horses in riding, as being more sure and easy in their motion, more capable of enduring fatigue, and of subsisting upon little nourishment. The *buffaloes* are generally of a gray colour, with horns almost straight, and are commonly sold at 10 taels per head. The *sheep* are of the broad-tailed species, and are said to become very fat in the mountain-pastures. The *hogs*, which are the most abundant of the tame animals, are generally of a black or white colour, and remarkably prolific, frequently producing seventeen or eighteen young at a litter. They are more cleanly in their habits than those of Europe, and are kept in the houses like dogs.

Birds. Water fowls.

Among the wild birds of China are eagles, falcons, pelicans, swans, storks, birds of paradise, paroquets, &c. The most beautiful of the feathered race in that country is the Kin-kee or *golden pheasant*, the body of which is finely shaped, its plumage inconceivably brilliant, and its flesh extremely delicate. The most courageous bird, and that which the Chinese consider as the sovereign of the birds of prey, is called hai-tsing, a species of *hawk*, said to be found only in the province of Shen-see, and always accounted the property of the emperor, to whose falconer it is required to be conveyed. Another of the more remarkable birds in the country, namely the fishing *corvorant*, called by the Chinese Leu-tze, has already been mentioned; and it may here only be added, that these birds are often as large as a goose, and so strong as to be able to raise from the water a fish of their own weight. Many of the *sparrows* are extremely beautiful, some having white breasts, some a green head and tail, and some the head, back, and top of the wings, of a purple colour. Immense numbers of herons, cranes, guillemots, and other aquatic fowls, frequent the extensive swamps of China; one of the most beautiful of which is the anas galericulata, usually called the *mandarin duck*, as it is generally bought by the higher classes to be kept in their aviaries.

Poultry.

The Chinese are in the practice of rearing numbers of poultry, pigeons, geese, quails, and particularly ducks. A live *quail* is commonly carried by the wealthier Chinese, in cold weather, instead of a muff. Next to the breeding of swine, the Chinese are much occupied with rearing *ducks*, which almost invariably compose one dish at the table of the higher classes. Many of the people of Canton earn a subsistence by rearing those creatures; some hatching their eggs in sand baths, arranged in ovens; some tending the young, inuring them to the water, and to the use of the young fry and craw-fish on the banks of the rivers; and some occupying themselves with feeding the flocks of the full grown fowls. In this latter business they take the ducks on board of a broad-bottomed boat, with a bridge, which lets down as a passage to the shore. The young brood are put under the guidance of an old duck, who leads them out to seek their food upon the beech and rice fields; and, upon receiving a signal, generally a whistle from the owner, brings them back to their proper sampane, which is then moved to another place in quest of more food.

---

* The tea plant at Sion, belonging to the Duke of Northumberland, is said to have been the first that flowered in Europe; but the finest known in England, was raised from seed in Kew gardens by Sir J. Ellis.

† For a more minute description of these and many other Chinese plants, shrubs, and trees, we must refer our readers to Osbeck's *Voyage to China*, passim, or Grosier's *Description of China*, vol. i. ad finem.

Fish.

The greater part of the best fish of Europe, the sturgeon, salmon, trout, herring, soal, pike, carp, &c. are affirmed by the French missionaries to abound in the lakes and rivers of China. The more remarkable, and the most esteemed as food, are the Tcho-kia-yu, that is the *fish in armour*, so named from its body being covered with sharp scales, the flesh of which resembles veal, and some of which are affirmed to weigh 40 lbs. The *flour fish*, so called from its white colour, great quantities of which are taken on the coasts of Kiangnan. The *pimoo-yu*, one of the most singular of the Chinese fishes, if their accounts could be credited, flat like the sole of a shoe, of a blackish colour, with only one eye, and without fins or scales on one of its sides; so as to have all the appearance of being only half a fish; and affirmed to be unable to swim, unless when united with a companion, when the two move on together as if forming only one individual. The Ming-foo-yoo, that is *the fish with the bright belly*, has a round head, a mouth like a falcon's beak, eight legs round its head, and two tufts of a beard, like two bunches of cord, by which it lays hold of the rocks, or bottom of the sea, when the water is strongly agitated, whence it is called by the Tartars Niomeré, or moored bark. The Kin-yu, or *gold fish*, which is kept for ornament in vases or small ponds, and which requires little other nourishment than the small worms and earthy particles found in the water, but which the Chinese sometimes feed by paste, snails, or lean pork dried and powdered. They are said to be so remarkably weak, as to be killed by a loud noise, a violent shaking of the vessel, or even by any very strong smell. Their spawn floats on the surface of the water, which they instantly devour; but if collected and exposed to the sun in a separate vessel, it is said that the young fry are thus produced. A fish resembling the Newfoundland *cod* is taken in great quantities on the coasts of Tche-ki-ang, and Fo-kien, salted, and sold throughout the empire at a low rate. A fish called *Hai-song*, or rather a shapeless, fishy mass, covered with excrescences like warts, is said to form a very common dish in China. It is killed by a very slight pressure, and, after being salted, is transported to every corner of the empire as a great delicacy, but was not much relished by the French missionaries. It is probably to this animal that Mr Barrow refers in these words: "Our old fisherman took out of the sea (among thousands which had floated round our vessel) one of those animal substances, which I believe are vulgarly called sea blubbers (mollusca medusa porpita.) It was at least a foot in diameter. Having dressed it for his supper, and seeing it wear the inviting appearance of a transparent colourless jelly, I was tempted to taste it; but the effect produced by this, or the fruit, or both, was a severe sickness, which continued for several days."

Insects.

Among the insect tribes, a variety of beautiful moths and butterflies abound in China, especially in the province of Quan-tong, where some of the latter are found of an extraordinary size, beginning to flutter about in the evening, but remaining motionless on the trees during the day, so as to be easily caught. *Silk insects*, resembling caterpillars, and somewhat different from the common silk-worm, are found in great numbers in the fields of Shang-tong. They propagate without culture, and feed upon the leaves of other trees, as well as those of the mulberry. They spin their silk, not in balls like the silk-worm, but in long filaments, which are caught by the trees and bushes as they are carried about by the wind. These are carefully collected and made into a kind of silk, which is very inferior in point of lustre, and resembles, at first view, coarse woollen or drugget, but which is often sold in China at a higher price than the finest satin, as it washes easily, lasts long, and is not so susceptible as other silks of being stained with oil. Upon a particular tree is found a kind of *nests*, called Oo-poey-tse, which are employed both as a medicine, and as dyeing materials. They appeared to European naturalists to resemble the excrescences upon the elm tree, usually called elm bladders, and were found to be much more astringent, than any other species of galls or vegetable substance yet known. The Chinese, however, consider them, not as excrescences, but as composed of a substance like wax, by certain insects, as a retreat for depositing their eggs, which have the appearance of fine dust, and with which these tubercles are filled. The largest of these tubercles are said to equal in size a man's fist, and the smallest to be as big as a chesnut. The Chinese collect them before the hoar frosts commence, destroy the worm within them by exposing them to the steam of boiling water, and then employ them as a black dye for paper or satin, or for their beards when they become grey. They are used also in medicine as remedies for hemorrhages, &c. and as antidotes to poisons. The *silk worm* of China has nothing peculiar. The houses, in which these insects are reared, are placed in the centre of the mulberry plantations, in order to be removed as far as possible from noise, as the bark of a dog, or a sudden shout, is often injurious to the young worms. They are watched with great attention night and day; and the young worms particularly are exposed to the sun in fine weather, upon thin gauze, stretched on wood or frames, and are replaced at night in the plantation houses.

View of the progressive intercourse of other nations with China.

China appears to have been totally unknown to the ancient Greeks, and is mentioned neither by Homer nor Herodotus. It has been conjectured, from a passage in Quintus Curtius, that Alexander the Great attained some knowledge of the Chinese during his conquests in India, about 327 years before Christ; and that it is to them the historian refers, in these words,—*hinc in regnum Sophitis perventum est. Gens, ut barbari, sapientia excellit, bonisque moribus regitur.*[*] In confirmation of this conjecture, it is added, that Strabo calls this kingdom of Sophites, Cathea, a word which is supposed to bear a resemblance to Cathay, the name given by the Tartars to China. The account, however, given by Quintus Curtius of the nation in question, does not apply so remarkably to the state and manners of the Chinese at that period, at least as described in their own histories; and his description, particularly, of the excellent dogs which they employed in hunting the lions, is utterly inapplicable to China, where we are assured that lions are not found; and where the figures of that animal upon their bridges, and other edifices, afford sufficient proof, that it has never ever been accurately described among them. Besides, it is to be observed, that, while Strabo gives the name of Cathea to the kingdom of Sophites, he fixes its situation between the rivers Hydaspes and Acesines.[†] It is the general opinion of the learned, that the Chinese are the same people with the Seres, mentioned by Horace, Virgil, Mela, Ammia-

Progressive intercourse with China.

nus Marcellinus, and particularly by Pliny, who mentions their gentle dispositions, their dislike of foreigners, and their silk manufactures. ‡ But not to insist, that Pliny's description applies rather more to the cotton tree than the silk worm, it is to be kept in view, that he proceeds to describe several other nations who dwelt beyond the Seres; a circumstance which could not be correctly affirmed of the Chinese, whose empire is bounded by the ocean on the east. About the year 126 before Christ, the Chinese are said to have extended their conquests so far to the west, as to have acquired some knowledge of Persia. ¶ The Parthians are said to have been known to the Chinese under the name of Gan-sie; and to have sent an embassy to the Emperor Han-tchang-tee, A. D. 88. Marcus Aurelius sent ambassadors to the Emperor Huon-tee, A. D. 166, who were called by the Chinese Ta-tsin, the People of the West; and from that period the Romans are said to have had a direct commercial intercourse with China, though much interrupted by the hostile measures of the Parthians and Persians. In 284, the Romans sent ambassadors to the Emperor Tsin-vootee; and, under the reign of Justinian, about the year 530, they first received silk worms from India, by means of two monks. In 567, Kosroe, king of Persia, sent an embassy to the Chinese, to engage them to take part with him against the Turks. In 643, the Romans sent another embassy, with presents, to the emperor of China.

The Arabs, having subjugated the kingdom of Persia, made their way to China, besieged and pillaged the city of Canton in 758. In 798, the Caliph Haroun sent ambassadors to the Chinese emperor, with a view to establish a commercial treaty; while the Romans, at the same time, carried on trade with them by sea, through the Persian Gulph; and this intercourse between China and the empire of Constantinople, continued to subsist till the invasion of Gengiz Khan, in 1211. Nicolas and Matthew Paul, or Polo, two Catholic missionaries, went to Tartary in 1260, proceeded to the court of Kublaikhan, and returned to Europe in 1272. They set out a second time, in company with Marco Polo, in 1274, and returned to Venice in 1295. In 1387, Tamerlane sent ambassadors to Tay-tsoo, the founder of the dynasty of Ming. In 1493, Bartholomew Diaz doubled the Cape of Good Hope; and in 1497, Vasco de Gama arrived in India. From that period, the European voyagers appeared in China, frequenting the ports of Canton and Ning-po. In 1517, Lopez de Souza sent from Goa a fleet of eight ships, conveying as an ambassador the Jesuit Thomas Pereira, who afterwards died at Pekin in prison. In 1563, the Portuguese obtained possession of Macao; and in 1573, the Jesuits formed an establishment on that settlement. In 1577, 1579, 1580, 1583, Fathers Herada, Marino, Alfara, Mendoza, and Ignatius, obtained admission into the Chinese dominions. In 1581, Father Roger, a French Jesuit, made his way into China, and Father Rici in 1582. In 1656, the first Dutch embassy arrived at Pekin, and resided there for the space of 91 days. In this embassy was Nieuhoff, the author of one of the earliest accounts of China. In 1667, another Dutch embassy appeared at Pekin, and remained 46 days. In 1693, the first Russian ambassadors entered China, under Isbrants Ides, a Dutchman, remaining 106 days. In 1720, the second Russian embassy, under Captain Ismailoff, arrived at Pekin, and remained 114 days. In the train of this embassy was Mr Bell of Antermony, an ingenious Scotch gentleman, whose travels from Petersburgh to Pekin afforded, at that period, so much new information respecting the Chinese empire. At the end of the same year arrived the Pope's nuncio Mezzabarba, and departed after a residence of 99 days. In 1753, the Portuguese embassy reached the Chinese metropolis, and remained only 39 days. In 1788, a Russian envoy resided at Pekin for the space of a year. In 1793, the British ambassador Lord Macartney was admitted to an audience of the Emperor Kien-long, and resided in Pekin 47 days. In the suite of his lordship were Sir George Staunton and Mr Barrow, two of the most intelligent writers on the state and character of the Chinese. In 1793, the third Dutch embassy, under M. Titzing, arrived at Pekin, making a residence of 36 days. In the suite of this embassy was the learned orientalist M. De Guignes the younger, whose travels to Pekin afford the most recent, and, in consequence of his long residence in China, the most accurate intelligence respecting that country.

Progressive intercourse with China.

All these different applications to the Chinese government, appear to have chiefly proceeded from commercial views; but not one of them succeeded in accomplishing any thing approaching to a treaty of alliance, or the establishment of a free trade, with that haughty and suspicious court. The Chinese, on their part, seem to have regarded, or at least to have invariably represented, all these embassies as tributary acknowledgments to the power and grandeur of their emperor; and to have considered these respective nations as highly honoured in having received permission to offer their presents to their mighty monarch. All these nations are upon an equally precarious footing, and exposed to an equally degrading treatment, in their commercial visits to Canton; and the extent of the mercantile transactions, which have been accomplished, in such inauspicious circumstances, may be regarded as a peculiarly striking specimen of the persevering ingenuity and accommodating spirit of European traders.

Portuguese.

The Portuguese were the first Europeans, who frequented the ports of China; and the viceroy of Goa, Lopez de Souza, aided by the talents and address of the Jesuit Pareira, procured a kind of commercial treaty in favour of his countrymen in the year 1517. But while the ambassador was on his way to Pekin, the Portuguese officers provoked their new allies by their insolent excesses, to drive them from their coasts, and left Pareira in the hands of the enraged Chinese, by whom he was thrown into prison, where he died in a very miserable condition, after a confinement of three years. Within a few years, however, the Portuguese again found means to procure permission to trade with the Chinese on the island of Tancian, and to erect tents on shore, while the ships were taking in their cargoes; when an unexpected opportunity of essentially serving the Chinese government, introduced them to a more permanent settlement in that country, than any other European nation has ever enjoyed. During the protracted war between the people of China and Japan, a pirate of the former nation named Tchang-see-lao, took possession of Macao, blockaded the mouth of the river at Canton, and even laid siege to that city in the year 1563. The mandarins, unable to withstand his fury, implored the assistance of the Portuguese, who made a successful attack upon his fleet, pursued him to Macao, and put him to death. In return for this signal service, they received from the Chinese emperor a perpetual grant of the island of Macao, where they form-

Progressive intercourse with China.

Macao.

ed a settlement, and built a city in the year 1585. This island, which is only about one league in length, and half a league in breadth, is separated from the continent of China by a small tongue of land, which is defended by a low dry stone wall, feebly garrisoned by a few Chinese troops. The Portuguese city was not surrounded with walls, and was merely protected by a few forts, till the year 1622, when it was attacked by a Dutch squadron, who were completely repulsed with a loss of 400 men, 100 of whom, being taken prisoners, were employed by the Portuguese in constructing two strong walls on the north and south sides of the city, which, with several other defences afterwards erected, have rendered the settlement of Macao sufficiently secure to resist all the attacks of the Chinese. This settlement continued to carry on a very flourishing commerce as long as the Portuguese preserved their intercourse with Japan; but it has of late greatly degenerated from its former activity and wealth. Its actual commerce is by no means extensive, consisting of a single ship sent annually to Goa, one to Timor, one or two to Bengal, as many to Manilla, and three or four to Cochinchina. One or two ships arrive yearly from Lisbon, loaded with tobacco from Brasil, for which there is a great demand in China, and return with different kinds of Chinese merchandise. The expence of the settlement, consisting chiefly in the salary of the governor and of other public functionaries, and the pay of the garrison, is defrayed by a duty of ten per cent. upon the cargoes of the shipping. The more wealthy part of the inhabitants either lend their money at good interest, or employ it in fitting out merchantmen, while the poorer classes perform the voyages, and live during the intervals upon their gains. All the shop-keepers and artisans are Chinese, as the Portuguese would reckon themselves disgraced by engaging in any kind of handicraft. There is a Chinese as well as a Portuguese governor at Macao, and when the respective interests of the two nations interfere, the Chinese generally stop the supply of provisions, and the Portuguese are obliged to purchase peace and plenty by means of their dollars, which are always acceptable to the mandarins. The population is estimated at 12,000, of which number 8000 are Chinese.

Dutch.

In the year 1602, the Dutch formed a company for the purpose of trading to India; and in 1607, they made their appearance for the first time at Macao. In 1609, they cruized along the coasts of China, and established a commercial intercourse with Japan. In 1620, they formed a settlement upon the island of Formosa; and, in 1622, made their unsuccessful attack upon Macao. In 1653, the governor of Batavia dispatched a frigate for the purpose of trading with the Chinese; and, in 1656 he sent the first Dutch embassy to Pekin, which failed in its object of procuring liberty to trade with the ports of China. In 1662, they were driven from Formosa, by the Chinese pirate Tching-tching-kong; and in 1673 they assisted the Chinese in an attack upon the son of Tching-tching-kong, called Coxinga, who then held the sovereignty of the island. From this period they made regular commercial voyages to China; and in 1740, when a number of Chinese had been massacred in Batavia, they sent a mission to Pekin, which sufficiently exculpated them to the Chinese court with respect to that affair, and prevented it from producing any interruption to their intercourse. In 1795, they sent their last embassy to the court of Pekin, which was productive of so little commercial benefit, while it was attended with so many circumstances degrading to their national character. Of all the foreign companies at Canton, the Dutch continued to carry on the most profitable and extensive commerce with the Chinese, till their affairs in that quarter of the globe became so much destroyed by the recent conquests of the British. Every year, they used to fit out three, four, or even five Indiamen, from 1000 to 1200 tons burden, for the Chinese trade. These ships, leaving Europe in the autumn, proceeded to Batavia, where they landed their hardware and the stores for the use of that settlement, reserving for the Chinese market, the woollens, gold-wire, copper, and ginseng, and replacing the unloaded goods with sandal wood, clove-buds, pepper, nutmeg, birds nests, tin, wax, and rice. These articles, procured by them at little expence, and so much in demand among the Chinese, yielded an immense profit; and their prudent attention, which other nations have been advised to imitate, in shewing equal favour to all the Hong merchants, prevented them from ever being entirely at the mercy of any of them, and procured them more beneficial contracts. They are charged, however, with erring egregiously in several essential points, with failing to pay sufficiently those, whom they employ, and thus exposing themselves to the evil of being badly served; with exercising too little precaution in the choice of their ship captains; with paying too little attention to the proper construction of their vessels; with interfering too minutely in prescribing their route; and with maintaining too many factors at Canton, and observing too many tedious forms in their commercial transactions.

British.

The English had made several detached voyages to India before the year 1600, but carried on no regular trade with that quarter of the globe, till the establishment of an East India Company by Queen Elizabeth, about the end of that year. In 1613, they obtained permission from the Emperor of Japan to establish a factory at Firando for purposes of commerce, but afterwards abandoned this privilege, without any reason being assigned. They experienced numberless obstacles in the progress of their India commerce, from the intrigues of the Dutch and Portuguese, in these countries; but finally succeeded in extending their trade to China. In 1634, Captain Weddel obtained permission from the Viceroy of Goa to sail for Macao, where he had to encounter every species of discouragement and delay in the prosecution of his views; but at length, without waiting for more particular permission, he dispatched some of his people up the river to Canton, who experienced a friendly reception from the Chinese, and laid the foundation of that intercourse, which has hitherto subsisted between the two nations. In the early periods of this navigation, the English visited the ports of Emooy in Fo-kien, and of Ning-po in Tche-kiang; and even erected a kind of lodging upon the island of Tcheoo-shan, upon which they had accidentally landed, while in quest of the entrance to the river of Ning-po; but the Chinese, having afterwards restricted all foreign traders to the port of Canton, they have continued, like the other nations who trade with China, to have only one factory at that city. Their great article of export from Canton is that of tea, of which they take on board annually about 20,000,000 of pounds in weight, besides raw silk, silk stuffs, sugarcandy, porcelain, camphor, nankeens, &c. for which they carry thither, besides money, lead, tin, woollen and cotton cloths, pepper, and other articles of merchandize. In this commerce, they employed, in 1795, twenty-one vessels, the amount of whose united burden was not less than 20,900 tons; but of this nearly one third was employed in commerce merely Indian, while the remaining two thirds conveyed the cargoes of Europe. A considerable portion of their imports to

Progressive intercourse with China.

China, especially the cotton, tin, pepper, &c. are carried from Madras, Bombay, Bencoolen, Surat, and the Straits of Sunda and Malacca; and it is this country-trade, from one part of India to another, which enables the British East India Company to maintain so brisk and lucrative a commerce with China. Their factory at Canton, which is the most expensive establishment of the kind, consists of twelve supercargoes and eight writers. The latter have only a small annual allowance and a free table; but succeed to the former by rotation. The former have also a free table at the expence of the East India Company, and divide annually among themselves, in shares proportioned to their seniority, a sum seldom less than £70,000, arising from a per centage on the value of import and export cargoes, producing to the chief of the factory from £10,000 to £12,000 per annum; and to the others from £1300 to £8000. Sir G. Staunton, junior, also was recently appointed Chinese interpreter and secretary to the factory, with a salary of £500 per annum.

French.

The establishment of an East India Company in France, first projected by Henry IV. in 1604, and afterwards canvassed under Louis XIII. in 1611, was at length effected in 1615, by a few merchants at Rouen. But their association failing in success, nothing effectual was done, notwithstanding all the exertions of Cardinal Richelieu, till Colbert issued letters patent for the creation of a new company in 1664. One association had been formed in 1660, a second in 1698, a third in 1713, which last was incorporated in 1719 into an East India Company. But this also having been abolished in 1796, the trade of France with China was carried on by a few private partnerships, till the year 1785, when a new company was created, which is said to have been badly organized from its foundation, and which was abrogated by a decree of the National Assembly in 1790, which pronounced the commerce of India beyond the Cape of Good Hope to be free to all the subjects of France. The French had, upon their first voyages to China, enjoyed the privilege, with other nations, of maintaining a factory at Canton; but, during the successive failures of their East India Companies, having been absent for a long period from the Chinese coasts, they were not permitted at their return to remain there as formerly; and it was not till the year 1728, that M. Duvelaer obtained permission to reside at Canton, from which, however, he was obliged, about three years after, to withdraw. In 1745, the French procured the privilege of landing on the island of Wampoo, upon paying 100 taels for each vessel; and their commerce never requires more than two or three ships from 700 to 800 tons each. The articles, which they used to carry out to China, were chiefly money, broad-cloth, looking-glasses, azure, gold-wire, and ebony; and those, which they brought back, were tea, raw-silk, silk-stuffs, nankeens, rhubarb, anise, and porcelain. Tea composed the third of the whole cargo, of which it is affirmed, that France itself did not consume above 300,000 pounds weight per annum, and that the remainder was thence exported to other countries.*

Danes.

In 1612, Christian IV. of Denmark issued a patent for the establishment of an East India Company in his dominions; but it was not till the year 1616 that any shipments were made for India. It appears, that the commerce of the Danes was very considerable about the year 1642, when the Dutch, who had then acquired the superiority in India, excluded them from several branches of traffic, while the wars in which their nation was involved in Europe at that period contributed no less powerfully to the diminution of their commercial undertakings. It was not till the year 1728, that their mercantile spirit revived under the powerful exertions of Christian V.; and it is from this period, that the intercourse of the Danes with China continued without interruption, till the late association of the Continental powers against Great Britain. They commonly fitted out two vessels annually for the port of Canton, where they used to maintain three residents, besides a supercargo, who went out and returned with each ship. But since the year 1795, they ceased to support a factory in China, on account of the great expence with which it is attended, and their commerce was conducted by persons annually sent out with their cargoes. These consisted principally of money, lead, amber, woollen stuffs, azure, and several articles of India merchandise taken on board at Tranquebar by one of the two vessels, while their principal article received in exchange was tea, which they afterwards transported to the north of Germany.

Progressive intercourse with China.

Swedes.

In 1626, Gustavus Adolphus issued an edict for the encouragement of commerce with India; but the wars which then raged in Germany prevented the execution of his plan. His successor, Queen Christina, was equally desirous to promote the same object; but the Dutch contrived to supplant the Swedes in all their measures to attain the end in view. Charles XI. and Charles XII. were so successively engaged in war, as to have no leisure for attending to mercantile interests, and by the loss of some of their best commercial provinces, they placed their subjects in a still more unfavourable situation for maritime enterprise. But at length, after the destruction of the Ostend India Company, in 1717, a Swedish merchant, named Koning, formed the plan of an East India Company in his own country, and obtained an edict for its establishment in 1731. From that period, the Swedes have traded with China; and generally fit out two vessels annually, laden with money, copper, lead, steel, and azure, receiving in return a cargo consisting chiefly of tea, which, like the Danes, they sell to the people in the north of Europe. They maintain three residents at Canton, besides a supercargo, who goes out and returns with each ship.

Merchants of Ostend.

In 1698, Charles II. of Spain, as sovereign of the Low Countries, established an East India Company at Ostend; but in consequence of the wars which then began to distract the adjacent kingdoms, nothing was attempted till the year 1717, when a few private individuals fitted out commercial expeditions. By the hostile measures, and political intrigues of the Dutch, the operations of this company were continually impeded; and though in 1723 they procured new letters patent from the court of Vienna, they were compelled, by the jealousy of their neighbours, to desist from the undertaking, and were finally dissolved in 1727. The same association was afterwards renewed in 1780, under the name of the Company of Trieste; but after a few voyages, they again deserted the Indian trade.

Prussians.

In 1751, the Prussians established at Embden an East India company, which merely sends a ship occasionally to China, with a cargo, consisting generally of money, ginseng, lead, and rice.

Spaniards.

The Spaniards have frequented the ports of China since their settlement at Manilla; but this trade was carried on merely by individual merchants, till 1733, when Philip V. made an unsuccessful attempt to form an East

Progressive intercourse with China.

Progressive intercourse with China.

India company, which was afterwards resumed, with better fortune, by Charles III. in 1785. The company established by this prince, possess the exclusive commerce with Asia, but are bound to land their return cargoes in Spain, and are permitted to export to other countries only such articles, as cannot be advantageously disposed of at home. They have a factory at Canton, with three supercargoes; who make no purchase in tea, but chiefly send home silk stuffs, nankeens, and other Chinese productions.

Americans. The first American ship, appeared in China in 1784; and, from that period, the traders of that country have continued to repair to Canton in considerable numbers. Their ships are the property of individuals; but it was not till the French revolution, that they were able to carry out any money, which is always the most necessary article in Chinese commerce.

Origin of companies. The first European traders to China, were generally private individuals, like the American merchants, who at present appear at Canton; but the length and dangers of the voyage, and the various difficulties which were encountered in such distant expeditions, rendered them gradually averse to the renewal of similar enterprises. It has been uniformly, therefore, found necessary in every country, with the exception of America, to commit the commerce of India to exclusive companies; and this single circumstance, the result of actual experience, ought not to be overlooked in the discussion of this much agitated question. Without attempting in this place to enter upon so important an enquiry as that of commercial monopolies, and with a full conviction of their injustice and inexpediency, in *general*, it would be wrong to conceal, that exclusive companies are pronounced by M. De Guignes to be necessary for carrying on an advantageous trade with India, and especially with China.

The Chinese themselves have found it requisite to form something like an exclusive company on their part, in trading with the foreign merchants who visit their ports. At first, these strangers were at liberty to address themselves indifferently to any of the Chinese, who could furnish the merchandize in demand. But, these private dealers frequently absconded with the property of the foreign trader, and repeated complaints were thus brought by the latter before the mandarins; who, on their part, were often sufficiently embarrassed with levying the customs from the numerous purchasers. With a view to relieve themselves from both these subjects of contention, they formed an association of Chinese merchants, to whom they committed the exclusive privilege of dealing with the Europeans, upon condition of their becoming responsible for the duties on the respective articles of merchandize. This society, denominated Cong-hang, was first instituted in 1759, by a Tsong-too, named Lee; and, among other regulations, they were expressly prohibited from furnishing the Europeans with goods upon credit, or receiving, on the other hand, any of their funds upon interest. The chiefs of the different trading companies are obliged to procure a Hong merchant to become surety for the payment of the duties, and to be responsible for any frauds or contests between the foreigners and the natives. The Hong merchant, on the other hand, is enjoined to give his consent to become Fiador or surety, to take charge of the interests of the stranger, to procure a Comprador or contractor for purchasing his provisions, and a Lingua or interpreter for transacting his affairs; and to see that all his accounts are settled before the departure of the vessel. The Europeans are farther required to present themselves at the custom-houses, for the purpose of being inspected,* and are forbidden to pass the appointed boundaries, unless when accompanied by a soldier. Neither are they allowed to possess a house of their own, upon the penalty of confiscation of goods to the purchaser, and of exile or death to the Chinese who shall have made such a sale; but the Hong merchants are bound to give a perpetual lease of a lodging to each nation, and to be responsible also for all, who are permitted to occupy it. By the same regulations, it was enacted, that no European should be permitted to bring his wife to any commercial place in the empire, especially the city of Canton; and that no ship should ascend the river, without first obtaining permission from the Chinese government, and taking on board a pilot accredited by the mandarins. No vessel belonging to a nation, who had residents at Canton, was allowed to disembark any article at Macao, but must repair to Wampoo, in order to be measured, and to pay the duties of anchorage. It was bound also to take a cargo in return, of which the Hong merchant was to be charged with the duties; and, if it should ever happen that such a vessel should depart in ballast, the Hong merchant was still to be responsible for the duties, in the same manner as if a cargo had been taken. All Europeans were farther ordained, upon the departure of their respective ships, to retire to Macao, and to lodge in houses belonging to the Portuguese, which the Chinese government engaged to procure to be let to the different companies. No European, upon his arrival, or during his residence in China, was to be allowed to monopolize any species of merchandize, either upon his own account, or for the purpose of transferring it to others; and the Hong merchants were forbidden to sell to foreigners either red or yellow copper, or to furnish each ship with more than 100 pounds of raw silk. The interpreters, contractors, and Chinese in general, were commanded not to enter into the service of a European, without first obtaining permission from the mandarins. These regulations have not always been faithfully observed; and both have Europeans occasionally made monopolies of particular goods, and the Hong merchants borrowed the funds of the foreigners at interest. Many of them have even failed to a considerable amount with the property of the strangers in their possession; and, though the Hong merchants were in those cases obliged to pay the debts of their associates, yet they always took care to reimburse themselves, by advancing the price of their teas and other articles of traffic. Nay, they often went so far as to fix, among themselves, the rate of all the exported and imported goods; and thus levied immense sums from the Europeans, which they employed in making presents to the mandarins, and in meeting the unexpected demands of their government. The number of these Hong merchants is not always the same. There were eight of them in the year 1784; but since that time, four additional have been created by the Hopoo, who finds this exercise of his power a very gainful practice. Though the Hong merchants only have the privilege of dealing with the Europeans, yet the latter may transact business with private merchants of the country.

---

* There are three custom-houses, where all, who pass in the Chinese boats between the ships and the town, are obliged to stop. They are built partly upon a rocky bank, and partly over the river, supported by piles. They have a bridge contrived in such a manner, that the boats may approach them at all times of the tide, as well during the ebb, as at the flood. Close to the house stands a flag marked with large Chinese characters, and their respective regulations are pasted upon the walls.

Commerce.

But few are ever permitted thus to interfere, except such as are actually brokers or factors, for the company of the Hong; and, though the government overlooks this species of unauthorized traffic, it is rather a hazardous speculation for the foreign trader; as, in the event of the Chinese dealer disappearing with his goods, he would not be allowed to make any application for redress. There is said to be little distinction made by the Hong merchants in their conduct to the different trading companies, except that they are disposed to give the preference to those, who bring into the market the largest sums of money, and who purchase the greatest quantities of tea.

Factories.

The factories or lodgings of the foreign traders are houses at the entrance of the suburbs of Canton, built close to the river, or over it, upon piles, and let by the Hong merchants to the European ships during their stay. They are only two stories high, but of very considerable length, one end stretching towards the river, and the other towards the factory street. They are built of unburnt bricks, and a great part of wood. They look like two houses built parallel and close to each other, with a court yard between them, which is paved like the floor of the ground story, with square or oblong stones, in which are little holes at certain distances, to let the water run through into the river. In every room, the foreign merchant finds a table, chairs, a bed with curtains of gauze or blue nankeen stuff, and a lamp fastened to the roof by means of a long rope. In the court yard are piled up the tea and porcelain chests, with other articles of merchandise; and in some parts of the yard are shades like coach-houses, with arched roofs for the protection of the goods from the weather. "A factory," says Osbeck, in his usually simple and descriptive style, "is mostly built in the following manner: Near the entrance of the street of the factory, on both sides of the gate, is a little apartment, upon which are commonly some papers with figures, like arms, and two round lanterns of bamboo, covered with skins; for glass or horn lanterns are quite unusual here. The gate of the factory is on the inside built over. Directly behind it stands a high board, almost as broad as the entrance, to hinder the people in the streets from looking into the yard or court, without being any obstacle to those who pass to and fro. In almost all corners are buckets, into which people make water, which is afterwards carried into the fields. The foremost rooms on the sides look like kitchens, and have rails before them. Farther on, quite across the court, in the second story, is an open hall, with a sort of gallery, upon which is an altar covered with flowers and incense, provided with a gilt picture and a table. Behind this, the yard is quite open in front, but on the sides are rooms both above and below. In the side roofs are here and there some lanterns of painted gauze, in some of which they burn lamps at night. Before the side roofs, and on their sides, are little gardens, with bamboo trees, citrons, and plaintains, and other trees already mentioned. The wall about these trees towards the yard is made of brick, which, except the foundation, are laid like lattice-work. Next to these gardens is an enclosed court-yard, and then an open one, with rooms and gardens for pleasure on the sides. The last of all is a hall in the second story across the yard, having rooms on its sides, which are fitted up for a dining-room. Below it is the kitchen, the watch-house of the sailors, and the lodging of the captain of the factory. The captain of the factory has a mate, who is to take care, that the sailors and Chinese workmen do their business; and he notes down those people, who come from or go to the ships with sampanes of burden. In the factories live the supercargo, the assistants, the purser, the cooks, and other servants, during the whole time of their stay; and besides them, those who come occasionally thither from the ships. There are continually some sailors, who watch with drawn swords in their hands, to hinder those from entering who have no right. They indicate the time upon the gong-gong; and beat upon it, as it were upon a drum, with sticks, when dinner or supper is ready. Every thing is carefully kept in the factories, both effects coming from the ships, viz. money, lead, cloth, raisins, almonds, &c. and those which are to be embarked, as porcelain, tea, silk, and many other things, which are brought on board by the sampanes of burden, after some mandarins, appointed for that purpose, have weighed them, and stamped a seal upon them. In each sampane, loaded with these and other things, goes a mandarin and some armed sailors, from the factory to the ship, to guard them, lest the master of the sampane should defraud them, as often happens, notwithstanding these regulations. The supercargo always sends a letter to the captain, or whoever has the command of the ship, with an account of all the boxes and packs, and the sailors bring an answer back. The flag of the factory stands on the water side, and is hoisted on all festivals." "The name we give to the Chinese servants is Kulier. These wait at table in the factories, bring in the meat, wash the dishes, &c. clean the knives and forks, fill the lamps in the yard and rooms with oil at night, clean the vessels, and do the like business; which the Chinese valets de chambre look upon as trifling in regard to sweeping the rooms, assisting in carrying the tea chests, and other wares in and out, &c. These and a Chinese cook are paid by the Company. Besides these, every one, or several together, hire a Chinese servant, who is paid some dollars per month. This person buys every thing you want, and frequently by this means avails himself more than by his wages. Happy is the man, who has not the misfortune of hiring a thief into his house; but often, however, it is the case."*

CHIPPENHAM, a town of England in Wiltshire, is delightfully situated on the river Avon, which is crossed by a handsome freestone bridge of twenty-one arches, decorated with balustrades and lamps. The principal street is about half a mile long, and the houses are in general neat and well built. The church is a venerable Gothic edifice, supposed to have been built by the Hungerford family; but the market-house is a mean building, unworthy of such a town. The manufacture of superfine woollen cloth, of the very best quality, is carried on here, to a considerable extent, and is in such a flourishing state, that the inferior classes, to whom it gives employment, can scarcely procure dwelling-houses for their families.

CHIVALRY.

Chivalry.

THERE is scarcely any subject of antiquarian research so free from the reproach of uninteresting and unprofitable labour, as that which relates to the origin, the causes, the institutions, and the effects of chivalry. Some of our earliest and most pleasing associations are connected with tales of romance; and even after our judgment is disposed to reject them as rude and extravagant, the subjects which the most admired poets, of almost every nation, have chosen, lead us back to our former pleasures; and strengthen the hold they have on our imaginations, by enlisting on their side the approbation of a refined and cultivated taste. Nor are the antiquarian researches, which have chivalry for their object, less interesting and instructive to the philosopher. If he wish to inform himself of the opinions, the manners, and the pursuits of nations, at different periods of their progress from barbarism and ignorance, to civilization and knowledge;—if he wish to analyse, and to account for, those great and leading points of character, which distinguish modern from ancient manners, he must go back to the age of chivalry. Courtesy of manners, the point of honour, a more jealous and habitual attachment to truth than obtained among the nations of antiquity, and a refined, respectful, and delicate gallantry, may be traced from the period when chivalry first dawned, to the present times.

Whoever is equally conversant with the early history of Greece and Rome, and with the history of those barbarians, who overran and conquered the empire of the latter, must be struck with the different manners that distinguished them; and if he trace these manners during the more advanced state of the ancient world, when every thing else indicated refinement and civilization, he will still detect the same want of courtesy, the same inattention and disregard to the rights and comforts of the female sex, and the same indifference about personal honour, which existed in the ruder state of their society; while, on the other hand, among the barbarians, far behind the inhabitants of Greece and Rome in every other respect, he will discover those traits of character, on which the most polished modern nations particularly pride themselves.

Chivalry, therefore, characterised as it has justly been by an elegant writer, as consisting "in a passion for arms; in a spirit of enterprise; in the honour of knighthood; in rewards of valour; in splendour of equipages; in romantic ideas of justice; in a passion for adventures; in an eagerness to run to the succour of the distressed; in a pride in redressing wrongs and removing grievances; in the courtesy, affability, and gallantry, for which those who attached themselves to it were distinguished; and in that character of religion, which was deeply imprinted on the minds of all knights, and was essential to their institution;"—as it constitutes one of the most remarkable features in the history of the ancestors of almost all European nations; as its effects on our opinions, habits, and manners, may still be traced; and as it is interwoven with our earliest associations, and with the highest charms of poetry of which modern times can boast—demands and deserves a full and patient investigation of its origin, causes, and institutions.

More difficulties arise in tracing and fixing the period of the origin of chivalry, than would at first be supposed. An institution so singular and striking, which stood forth amidst ignorance, rudeness, and barbarism, distinguished for its refinement and elegance; and which forms the subject, in a greater or less degree, of almost every writer, during the period at which it flourished, it might have been naturally imagined, would have been described, and could therefore have been detected in its infancy. This, however, is not the case. Almost every distinguishing feature of it may indeed be found in the manners and institutions of different nations, and at very early periods; but chivalry, "properly so called, and under the idea of a distinct military order, conferred in the way of investiture, and accompanied with the solemnity of an oath, as described in the old historians and romancers;" is not distinctly mentioned till it evidently had attained its full form, and taken deep and extensive root in almost every part of Europe.

Theories of the origin of chivalry.

In this obscurity and uncertainty of historical record, several theories have been advanced, to account for the origin of chivalry, and to fix the period, and the nation, to which it owes its birth, or at least its full maturity. Warburton, in the *Supplement to Jarvis' Preface* to his translation of Don Quixotte, and in his final note to *Love's Labour Lost*, advances and maintains the hypothesis, which had been previously thrown out by Velasquez, in his *History of Spanish Poetry*, that romance rhime, and knighthood, originated with the Arabians, and through them were introduced, first into Spain, and afterwards into France and the rest of Europe. Mallet, in his *Introduction to the History of Denmark*, sometimes directly maintains the opinion, and in other parts of his work, throws out hints, which lead to the same conclusion that chivalry originated with the Scandinavians. Percy, in his *Reliques of Ancient Poetry*, and Pinkerton, in his *Dissertation on the Goths and Scythians*, mould into a regular and complete hypothesis the opinion of Mallet; the former supporting it with much ingenuity and learning; the latter, in his accustomed manner, with dogmatic authority. Warton, in the first *Dissertation* prefixed to his *History of English Poetry*; and occasionally and incidentally in the third section of the History, offers a modification, or rather an admixture of the hypothesis of Warburton and Mallet, tracing chivalry originally to the East, but deriving it from that quarter, partly through the medium of the Arabians, on their conquest of Spain, and partly through Odin and his followers, when they emigrated from Asia to the north of Europe. Herder, also, in his *Outlines of a Philosophy of the History of Man*, unites and adopts the two hypotheses, and ascribes the life and body which was given to chivalry, as arising from a concurrence of causes, proceeding from "two extremities of the earth," from Arabia through Spain, and from the Normans on their settlement in France. Lastly, a very learned and ingenious writer in the *Monthly Magazine* for February 1800, rejecting all the former hypotheses, considers Armorica, and the connected provinces of Britain, as the countries which gave "the very decisive impulse to the character of modern civilization," by the introduction of romance, rhime, and knighthood.

In order that the respective merits of these different hypotheses may be examined with due candour, and upon sufficient ground, it will be proper to collect and arrange the traces of chivalry, which are to be found in the history of the different countries, from which each hypothesis derives its origin. Thus the whole weight and bearing of authority will be given to the opinions of the writers we have named; and after an attentive and comparative examination, we may be enabled to decide on their respective merits, and probably to throw a new and additional light on this important but obscure subject. Many of the traces of chivalry, which we shall notice and illustrate, have not been even incidentally alluded to, by the authors, whose opinions they confirm; in this respect, therefore, the plan we propose to follow will be useful; while to those who are anxious to investigate the manners of different and distant nations, and by detecting similar opinions and usages among them, to prove their affinity, the enquiry will be interesting and important.

Before entering on this part of the subject, it may be useful to recal to our recollection, what are the distinguishing features of chivalry; viz. a romantic spirit of adventure, and love of arms; courtesy of manners; the point of honour; and a devoted and respectful attachment to the female sex. There are subordinate points, which naturally spring from this pervading spirit; such as a love of the show of war in times of peace, by means of tournaments; a strong and zealous attachment among those who professed chivalry; and the principal and distinguishing ceremonies by which the privileges of knighthood were conferred, and its duties rendered obligatory.

Traces of chivalry in the East.

If we examine into the traces of chivalry in the East, in order to appreciate what degree of plausibility is due to the hypothesis of Warburton, the first circumstance which strikes us, is the frequent mention and description in the poems and romances of the Arabians and Persians, particularly in the *Shah Namè*, of single combats. The persons who engaged in them, like the heroes of chivalry, were armed with complete coats of mail: they had plumed helmets, spears, swords, maces, and shields, and even the dagger, such a principal instrument in all single combats among the knights of chivalry. With respect to their armour, there was only one point in which they differed:—the bow and arrow was never used by European knights, they being confined to the infantry; whereas the Asiatic champions, in addition to the arms already mentioned, had also these weapons. One combat is particularly mentioned by Persian writers, between twelve warriors of Persia and twelve of Tartary; and one of the Persian warriors seems, from his name, to have been a knight errant, as he was known by the appellation of *Reym Khah*, one who goes in search of adventures. Dr Herbelot, also, in his *Bibliotheque Orientale*, under the article *Batthal*, explains it to mean a brave and valiant man, who went in search of adventures, in the same manner as the knight errants of the ancient romances.

In another respect, these combats in the East were very similar to those which formed the glory and principal employment of the knights of chivalry. The Eastern heroes used great precautions to secure themselves from spells and enchantments; and in the West, before the combat began, the champion took an oath, not to carry about him any herb, spell, or enchantment, by which he might procure victory.

On this point of resemblance, Warburton has offered a remark in his final note to *Love's Labour Lost*, which perhaps ought to be considered, rather, however, out of respect to that author's character for learning, than on account of its relevancy and solidity. Of the other illustrations and proofs which he has brought forward in support of his hypothesis of the Eastern origin of romance and chivalry, Mr Tyrwhitt has given a full and satisfactory refutation; the one we are about to cite and consider, has escaped the notice and castigation of that acute writer. "Chivalry, (says Warburton), without a Saracen, was so very lame and imperfect a thing, that even the wooden image which turned round on an axis, and served the knights to try their swords, and break their lances upon, was called by the Italians and Spaniards, *Saricino*, and *Sarazino*, so closely were these two ideas connected.

Now, in the first place, this argument, if well founded, would bring the origin of chivalry down to a period posterior to the Crusades; for till they took place, it is hardly to be supposed that a word borrowed from those against whom the Christians were engaged, would be employed. In illustration of this remark, it may be observed, that *after* the Crusades, the phrase *Jeu Sarrazionois* was in general use, to express any sharp engagement; and allusions to the Saracens became very common in the romances of that period.

In the second place, *Sarazino* was by no means a common name for the image, on which the knights broke their lances; nor were images of men, commonly used for this purpose, (if we may credit the testimony of Matthew Paris), in the early days of chivalry; for that author informs us, that the image of a peacock, the bird served up at the most solemn feasts of chivalry, and by which the most sacred vows were taken, was employed on this occasion.

But lastly, even if we grant that the wooden image was generally called *Sarazino*, this by no means proves the position of Warburton: it is certainly much more natural to suppose, that the name of that enemy against whom the knights in real warfare were to be employed, was given to the wooden image out of contempt or detestation, than that it was thus bestowed, because the institution of chivalry was borrowed from the Saracens.

The traces of the eastern origin of chivalry, besides being derived directly from Arabia and Persia, are supposed to be found in the early periods of Spanish history, immediately after the conquest of that country by the Saracens. But these traces are very indistinct and feeble. The *Moriscoes*, or song romances of Spain, bear but a faint resemblance to the romances of chivalry:—the *Fiestas de los canas* may be compared with more propriety to the Gothic tournaments; but the resemblance is not such as would justify the inference, that the latter was derived from the former.

After all, however, the points of resemblance between the chivalry of the East and the West are very few, and consist in circumstances of the smallest importance, and of the least characteristic peculiarity. A fondness for feats of arms, and amusements which discovered and gratified that fondness, may be traced in the history and romances of the East; but the master spirit of European chivalry, the point of honour, courtesy of manners, and, above all, attentive and respectful gallantry, must not be sought for among the eastern nations.

Traces of chivalry among the Scandinavians.

If we examine the manners and customs of the Scandinavian nations, in order to ascertain what traces and resemblances of chivalry they afford, we shall discover many more of its peculiar features, than the manners and customs of the eastern nations presented. The age at which the Scandinavian youth became their own masters, and authorised to engage in war, and the manner in which this ceremony was performed, coincide with the institutions of chivalry. At the age of fifteen, they were presented with a sword, a buckler, and a lance, and from that period they became members of the state. The heroes of chivalry gave names to their swords;—this, too, was done by the ancient Scandinavian heroes. The following passage, from the Edda, proves that the amusements of the Scandinavians were of the same warlike character as those in which the knights of chivalry engaged: "But tell me, how do the heroes divert themselves when they are not drinking? Every day," replies Har, "as soon as they have drest themselves, they take their arms, and, entering the lists, fight till they cut one another in pieces." And Isidore, in his Chronicle, says, that, in his time, "the Goths were extremely fond of fighting, of handling their arms, and throwing their darts; and that it was their daily practice to divert themselves with mock-fighting."

But as the grand characteristics of chivalry were the points of honour and gallantry united to war, it is necessary to attend to these features in the Scandinavian tribes. Among them, nothing was deemed so insulting as to call a man "niding," or infamous; "for he who had received so deep a stain, without endeavouring to wash it out with the blood of his adversary, would have lost much more than the life he was so desirous to save. Banished by public indignation from the society of men, degraded from his quality of citizen, and scarcely regarded as a human creature, he had nothing left for it, but a shameful and insecure flight:" (*Mallet*, i. 219.) That feeling of honour, which renders life but a secondary object, by making character dearer than life, which marked the age of chivalry, and which has descended from it to modern times, is here strongly and justly painted, as forming a leading and conspicuous feature in the manners and principles of the Scandinavians. Nor were the women less sensible of the value and importance of honour than the men; they were early and regularly taught to despise such as spent their lives in idleness and obscurity;—to prize and reward the valiant, and to shun the cowardly. Such also were the ladies in the age of chivalry.

A delicate and respectful gallantry, even in the days of Tacitus, marked the Gothic nations; and was deemed a necessary appendage, as it was almost always the proof of enterprise and valour. If the knights of chivalry, for the sake of their favourite ladies, went in quest of adventures, and sought victory and renown in foreign lands, and in the midst of difficulty and danger, so also did the Scandinavian heroes. The ode of Regner Lodbrof, so renowned in Scandinavian story, presents us with an instance of gallantry very similar to those which are found in the romances of chivalry, and which we know to have been inculcated by the spirit of that institution. A Swedish princess was forcibly detained by one of her father's captains in an impregnable fortress. He that should rescue the lady, was promised by her father her hand in marriage. Regner undertook and succeeded in the enterprize, and obtained the lady. In the song of chivalry, written by Harold the Valiant, which, as Warton justly observes, has the romantic air of a set of stanzas composed by a provincial Troubadour, he enumerates and describes all the different feats of valour and enterprise, which he had performed for the purpose of obtaining the favour of his mistress.

As respect for the female sex is one of the principal points of resemblance between the manners of the Scandinavian nations and the institutions of chivalry, it may further be remarked, that, according to the testimony of Salvian, the Goths, when they became masters of the Roman provinces, not only abstained from violating the chastity of the women, but, by their example, and the severity of their discipline, rendered the Romans themselves chaste. To protect the chastity of the women was one of the principal articles in the vow that was taken by a knight, when he was admitted into the order of chivalry.

There are still one or two other circumstances of inferior importance, and of a detached nature, by means of which the manners of the Scandinavian tribes may be connected with the institutions and ceremonies of chivalry. When a knight entered on any engagement, to the performance of which he bound himself by a solemn vow, he put chains sometimes on his arm, and sometimes on his foot, which he durst not remove till he had fulfilled his vow, or till he could transfer them to another knight, whom he had overcome in battle or single combat. Tacitus, in his account of the manners of the Germans, relates that the Catti, a tribe of that nation, wore a ring, which they viewed as ignominious, and from which they could not be liberated, till they had distinguished themselves by the slaughter of an enemy.

In the History of Charles and Grymer, Swedish kings, and of Hialmar, the son of Harci, King Biarmland, which evidently describes the manners of Scandinavia during the continuance of the Pagan religion, and in times preceding the tenth century, Hialmar proposes to Grymer to enter into strict brotherly confederacy, which was evidently of the same nature as those fraternities in arms which occur so frequently in the history of chivalry in France and England. Keysler, in his *Antiquitates Septentrionales*, informs us, that the ceremonies used in entering into those fraternities were similar to those employed in the days of chivalry; and the most singular and remarkable of those ceremonies, the admixture of the blood of those who were to compose the brotherhood, is described by Herodotus, as having been usual among the Scythians, the ancestors of the Goths, on the same occasion.

Traces of chivalry in Armorica.

It now remains to examine the manners and institutions of Armorica, in order that we may be enabled to detect in them whatever traces they may exhibit of the features of chivalry. The name of Armorica is supposed to be of Celtic origin, and to signify the country near the sea; for more than 800 years, under that appellation, was comprehended all that part of France which is bounded by the Seine on the east, the Loire on the south, and the sea on the north and the west; including therefore Brittany, the greatest part of Normandy, Maine, Perche, and the northern part of Anjou and of Tourraine. In a more strict and limited sense, however, Armorica comprehended that province of France, which, from the end of the fourth century, was called Brittany.

The inhabitants of this part of France are of Celtic origin; and, in comparing their manners and institutions with those of chivalry, we must therefore have recourse to what we know of the manners and institutions of the Celtic tribes in general, as well as of those of Armorica in particular.

Among the Celtic nations, as well as among those of eastern and northern origin, feats of arms were a regular and honourable employment. The *Oryds* of the Welsh, like the knights of chivalry, rose to that rank through different degrees of honour, and were admitted into it by a ceremony very similar to that which was used in chivalry. They were taught the use of arms; and, like the knights errant, were clothed in green. The gold chain, which has already been noticed in treating of the manners of the Scandinavian nations, was used by the Celtic knights,—but rather as an ornament, and for the purpose of bestowing it as the prize of valour, or the reward of minstrelsy, than as the badge of an unperformed vow. An order of men, similar to the Scalds of the northern nations and the minstrels of chivalry, were educated among the Welsh and the other Celtic tribes, for the purpose of indulging the passions of the *Oryds* for public recitations in rhyme.

These features, however, in the manners of the Celtic tribes, are very general, and by no means sufficient to establish a striking and undisputed resemblance between them and the institutions of chivalry; much less to prove that chivalry originated with the people of Armorica, or the Celtic inhabitants of Wales and Cornwall. There is, however, another circumstance on which the ingenious and learned supporter of this hypothesis rests, in order to establish his position, which, though not immediately connected with our present subject, ought not to be passed over. He contends, and with much felicity and strength of illustration, that the oldest romances of chivalry are of Armorican origin. The steps by which he endeavours to make good his position are, 1st, that all the European nations take their romances of chivalry from the French; 2d, that the French romances originate in the north of France; and, 3d, that the older romances of chivalry have especially celebrated the heroes of Greater or Lesser Brittany, and are therefore of Armorican origin. But it is evident, that it by no means follows, because romances of chivalry are of Armorican origin, that chivalry itself sprung from the same country. This circumstance might strengthen other arguments, but it cannot of itself constitute an irrefragable and conclusive argument. Another position of the same writer is certainly unsupported by fact, and even were it true and well founded, it is not easy to perceive how it could strengthen his hypothesis. In order to prove that chivalry is not Scandinavian, but of Armorican origin, he asserts, that "the whole ritual of chivalry, the military exercises, the fortified palaces, its very religiosity, imply an advanced state in society, to which the Scandinavians could not have attained;" and the obligations of the knight, to which his oath bound him, he considers as the reliques of a receding, rather than the tokens of a growing civilization. This opinion is singular, and seems utterly void of foundation; but were it correct, what proof is there that the people of Armorica exhibited symptoms of a receding civilization, at the time when the people of Scandinavia were only advancing in civilization?

But in the manners and institutions of the Celtic nations, there is no proof of the existence of those peculiar qualities of chivalry:—a high sense of honour, courtesy of manners, and a refined and respectful gallantry; with regard to the latter, the Celtic nations, from every evidence, were far behind the Gothic tribes.

Inferences for fixing the origin of chivalry.

From the preceding investigation into the manners and institutions of the eastern, northern, and Celtic nations, so far as they appeared to bear a resemblance to the manners and institutions of chivalry, several inferences may be drawn, which will be of use in fixing its origin and tracing its causes.

In the first place, the high estimation in which valour was held by the eastern, northern, and Celtic nations, and their fondness for feats of arms, proves neither that these nations sprung from a common stock, nor that either of them gave birth to chivalry. The very constitution and circumstances of society, at the period to which our investigations referred, rendered valour indispensably necessary, and of paramount importance and honour; while the desire of keeping alive and improving their skill in fighting, and the habits they had acquired in actual warfare, naturally gave rise to feats of arms. These features in chivalry, therefore, were rather features of the age, and were exhibited with more prominence by those who had become knights, only because their rank and station in society called for greater skill and courage.

In the second place, the same remark will not apply with equal propriety and force to the more peculiar characteristics of chivalry—a high sense of honour, courtesy of manners, and especially delicate and respectful attention to the female sex. These are not to be found among most nations during that stage of society, in which they appeared among the Gothic tribes. It may be urged, indeed, that the violence and rapine of those barbarous ages required that especial protection should be shewn to the female sex; but this protection would not have been shown, unless their character had previously stood much higher with the men of this nation, than it did among the Greeks, Romans, and the people of the East. Besides, among the Gothic tribes, and in the days of chivalry, the female sex was not merely protected from violence, but they possessed a station of high importance and influence, and were regarded as the most proper and honourable rewarders of that valour, on which the men most highly prided themselves.

In the third place, chivalry, strictly and properly so called, cannot be traced among the institutions of any of the different nations whom we have considered. It nowhere appears as a whole, embodied into form, and infused with an active and animating spirit; the *disjecta membra* may be found, but even these are not complete; nor of that due proportion which they assumed, when chivalry was reduced to a system.

Lastly, in order to gain a clearer insight into the period and the nation that gave rise to chivalry, properly so called, it is necessary carefully to distinguish between a similarity of forms, ceremonies, and amusements, and a similarity in character, and in the nature of the principles and duties of the times, when chivalry actually flourished, and when it is supposed first to have appeared. In this, as in all other questions of antiquarian research, recourse must be had, in the first instance, to direct historical evidence, if it is to be found;—if this does not exist, internal and collateral evidence must be had recourse to, which divides itself into two species; that which consists in the nature of the amusements and ceremonies, and that which consists in the character and habits of nations. On the question of the origin of chivalry, direct historical evidence fails us. Among different nations, very far removed from each other in position, as well as in general habits, we can trace many of the amusements, and some features of the character of chivalry; but these, as has been already observed, were the necessary consequence of the circumstances, in which, at a certain stage of society, almost all nations are placed;—it is only among the people of one tribe, and among them from the earliest notice we possess respecting them, that those characteristics of chivalry, which strike us as the most singular and uncommon, are to be clearly traced.

Still, however, the period when chivalry became a regular and systematic institution remains to be fixed;—that the great principles of it are of Gothic origin, seems to rest on as satisfactory a degree of evidence as the nature of the question will admit; but the state of society among the Goths, at the period when we can trace the peculiar features of chivalry among them, was not such, as either to call for its complete and regular institution, or to enable them to have brought it about. The different periods, which have been assigned to the regular institution of chivalry, are all connected by the authors, who respectively advance and maintain them with some theory on that subject. Those who maintain that chivalry arose out of the feudal system, fix the period of its regular institution after the time of Charlemagne, when that system began to operate most powerfully on the manners and laws of Europe. By other writers, the institution of chivalry is supposed to have been a consequence of the Crusades; and a period subsequent to them is of course assigned to the origin of regular chivalry. Lastly, those who are of opinion, not only that traces of chivalry may be perceived scattered among the manners and institutions of the Scandinavians, but that it existed in a regular and complete form among that people, are disposed naturally to fix the period of its origin prior to the time of Charlemagne.

We shall, in the first place, attend to the evidence on which the opinion of its origin prior to the time of Charlemagne rests; but before examining it, it is necessary to call to mind a position already laid down, viz. that similarity in the peculiar features of chivalry, and not a mere resemblance of a general and uncharacteristic nature, must alone be admitted as relevant and satisfactory evidence.

In describing the manners and customs of the Scandinavian nations, their mode of admitting their young men to the honour and the use of arms was particularly noticed. The advocates for the opinion under examination contend, that this ceremony gradually acquired, long before the time of Charlemagne, all that form and significancy, which it possessed in the most flourishing days of chivalry. It may, therefore, be proper to examine some of the facts on which they build this opinion, since it is of the utmost consequence to distinguish between the ceremonies which attended the investiture of the youth with arms, and his adoption into the order of military men, and those ceremonies with which he was admitted to the rank and privileges, and by which he bound himself to discharge the duties of chivalry.

One of the earliest, best authenticated, and most particular and appropriate instances, is supplied by Cassiodorus. This author informs us, that Theodoric, king of the Ostrogoths, adopted the king of the Heruli, by investing him with a sword, a shield, and other instruments of war; and by presenting him with a horse. A short time afterwards, the Emperor Justinian used similar ceremonies, in adopting Eutharic, the father of Athalaric, king of the same nation. These facts point out the mode used in the 6th century. In the subsequent century, it would appear from a passage in the life of St Eloi by St Owen, that a further advance had been made towards the ceremonies employed in the acknowledged period of chivalry, by distinguishing the knight with ornaments of gold. The passage, however, on which this opinion is grounded,—"non esse dignum, hos qui seculo militarent, incedere *inauratos*," is proved by Mon. de St Palaye, to have been altered in its most important word, since *inornatos*, and not *inauratos* is the original and genuine reading.

It must not be concealed, however, that as we approach the times of Charlemagne, not only do instances of military investiture occur more frequently, but they were attended with much more solemnity and pomp, and with the addition of these ceremonies, which are among the most striking and characteristic of chivalry. Charlemagne sent for his son Louis from Aquitaine, expressly for the purpose of investing him; and at the investiture great splendour and ceremony were used. Similar splendour and ceremony were employed by Louis, when he invested his son Charles. But the instance most to the point, as supplying a decisive proof of the addition of a ceremony very striking in chivalry, is given by Mennenius in the *Reports of Friesland*, as taken from a cotemporary monument, (A. D. 802). Charlemagne, among the other privileges which he granted to that part of his empire, expressly ordained that the governor might make knights, by girding them with a sword, and *giving them a blow*; and this last part of the ceremony is described as customary,—*dato eisdem, sicut consuetudinis est, manu colapho.*

Such is the substance and general bearing and weight of the facts on which the opinion is grounded, that chivalry existed prior to the time of Charlemagne; that it was indeed gradually rendered more perfect in its ceremonies, but that its principle and characteristics were in existence before the reign of that monarch. But, on considering what has been advanced, it will be found to prove merely, that military investiture, a custom existing in a rude form among the Germans at the time of Tacitus, and necessarily arising out of the state and circumstances of society, gradually assumed more splendour, and was attended with additional ceremonies, all indicative of the admission of the person invested, into the rank of military men. But the principal circumstance we shall look for in vain; there is no proof that other duties than those of a purely military character, and of these, only such as the sovereign called for, were undertaken by those who were so invested.

If chivalry existed prior to the regular and full establishment and operation of the feudal system, and was derived, in its perfect state, from the Scandinavians, we should be able to trace it in England before the conquest. On the continent, it may be difficult to determine, whether it owed its origin to the feudal system, or how far that system, co-operating with other antecedent or cotemporary causes, modified and perfected it; because it is not easy to fix the time when the feudal system was in full and regular operation there: but it is well known that in England this system did not exist till the conquest, and that it was introduced and established by William. It is therefore necessary to examine those instances of investiture of which history informs us before the conquest, in order that it may be determined whether they were purely military, or whether in their nature and object they resembled the ceremonies, and were intended to impose the obligations and duties of chivalry. There are only two instances in the Anglo-Saxon period of the English history of investiture. The most ancient occurs in the time of Alfred, and is related by William of Malmesbury: that monarch, struck with the appearance and character of Athelstan, made him a *miles* before the prescribed and usual age, by investing him with a purple garment, a belt adorned with gems, and a Saxon sword with a golden scabbard. In this account there are certainly no traces of chivalry. The investiture was purely military; it had not even many of the ceremonies of chivalry, and does not appear to have imposed any of its peculiar duties. The other instance occurred subsequently, in the time of Edward the Confessor, and is recorded much more fully by Ingulphus. In giving an account of Hereward, who had distinguished himself by his prowess and his victories, he says, that as, notwithstanding the military command he possessed, he had not yet been legally bound with the belt, according to the established custom, he resolved to undergo that ceremony; for it was the custom of the English, (adds Ingulphus,) that whoever meant to be legally consecrated to warfare, should, on the eve of the day appointed for his consecration, confess all his sins to some priest; and afterwards spend the night in the church, in prayer and mortification; on the morrow, after having attended mass, he should offer his sword on the altar, and the gospel being read, the priest should place the sword, having blest it, on the neck of the soldier (*miles*) bestowing on him at the same time, his benediction." Ingulphus concludes this account with observing, that the Normans abominating this mode of consecrating a *miles*, considered the person so consecrated not as a legitimate *miles*, but as a degenerated and slothful knight. The part of the ceremony which the Normans objected to, was that which vested the power of making a *miles* with the priesthood, not the forms which were passed through; and accordingly soon after the establishment of the Norman power in England, the privilege of making knights was virtually, though not expressly taken from that order.

Chivalry supposed to take its rise from the Crusades.

The instance quoted from Ingulphus, is by no means sufficient to prove the existence of chivalry in England before the Conquest. The ceremonies, indeed, are similar, but there is no mention of the duties imposed by chivalry; and what is still more decisive of the question, Ingulphus expressly points out the object and effect of the consecration, viz. that the person so consecrated, might legitimately engage in warfare. Here, then, we have only military investiture, but no traces of the spirit and genius of chivalry. That high regard for their honour, and that refined and enthusiastic gallantry which may be traced in the manners of the Scandinavian nations, was not yet expressly and solemnly incorporated with the love of military enterprise, so common and so necessary to all barbarous nations. The opinion that chivalry took its rise from the Crusades, is advanced by a friend of Bishop Hurd's, in his *Letters on Chivalry and Romance*; and, although no attempt is made to support it, by the evidence of cotemporary authors, yet the ingenuity with which it is maintained, by means of presumptive evidence, renders it deserving of some notice.

The advocate of this opinion supposes, that the restless spirit of the vassals of the Gothic princes, which had been checked and retarded by the Crusades, broke out, when they were no longer engaged in them, in all the extravagancies of knight-errantry. That the warlike and restless genius of the feudatories took this turn, he ascribes to the military fame they had acquired in the Holy Land, and the love and passion of enterprise with which the Crusades had inspired them. "Their late expeditions had given them a turn for roving in quest of adventures; and their religious zeal had infused high notions of piety, justice, and chastity."

"The scene of action being now more confined, they turned themselves from the *world's debate* to private and personal animosities. Chivalry was employed in rescuing humble and faithful vassals from the oppression of petty lords; their women from savage lust; and the hoary heads of hermits (a species of eastern monks much reverenced in the Holy Land,) from rapine and outrage.

"In the mean time, the courts of the feudal sovereigns grew magnificent and polite; and, as the military constitution still subsisted, military merit was to be upheld; but wanting its old objects, it naturally softened into the fictitious images and courtly exercises of war, in *justs* and *tournaments*, where the honour of the ladies supplied the place of zeal for the holy sepulchre; and thus the courtesy of elegant love, but of a wild and fanatic species, as being engrafted on spiritual enthusiasm, came to mix itself with the other characters of the knight-errants."

But this opinion, however plausible, will not bear the test either of argument or authority. Bishop Hurd justly remarks, "that unless the seeds of that spirit, which appeared in the Crusades, had been plentifully sown, and indeed grown up to some maturity in the feudal times preceding that event, it would not have been possible for the western princes to give that politic diversion to their turbulent vassals, which the new hypothesis supposes." And there is undoubted evidence that chivalry, "in its most peculiar and characteristic forms," existed at least as early as the beginning of the eleventh century. Besides, in the accounts which we have of the first Crusades, evident traces are to be found of this institution full formed, and operating with powerful influence on the manners and pursuits of the knights who embarked in it.

Chivalry supposed to arise from the feudal system.

It now remains to consider the opinion of those, who maintain that chivalry was the natural effect of the feudal policy, and who consequently fix its origin at that period, when this policy was in full establishment and complete operation.

The feudal policy may be regarded, either as the cause of the ceremonies and institutions of chivalry only, or of its spirit and characteristic principles. In the former point of view, it would naturally add to the solemnity of military investiture. As, under the feudal system, those lands which belonged to minors were held by the sovereign, till the owner was able to discharge the military duties connected with their possession, the period assigned by law, at which he was deemed capable of defending his land with *complete arms*, or with those which a knight was entitled to wear, and at which the sovereign resigned it with his possession, would naturally be celebrated with great pomp and solemnity.

But the influence of the feudal system in giving form and spirit to the institutions of chivalry, was much more conspicuous and important. That passion for military adventure, which may be traced in almost every nation, at a certain stage of their progress towards civilization, would be much increased by the principles and effects of the feudal system. The territory each noble possessed had been gained by the sword; the acknowledgment he paid for it, was the employment of his sword in the service of his sovereign; and by the same means alone, could it be defended from the attacks of his restless and powerful neighbours. Much of his time, therefore, must have been taken up in actual warfare; and what was not thus employed, was naturally devoted to those amusements, which would increase his military skill, and which bore the semblance of war.

That high sense of honour, and that pride in redressing wrongs and removing grievances, which distinguished the Scandinavian nations, would have ample scope during the violence, rapine, and plunder of the feudal state; while the attentive and respectful gallantry which was equally conspicuous among them, would be cherished and called into constant exercise in the castles of the barons, amidst the free commerce and conversation of the ladies. The religious character which distinguished chivalry, arose out of the manners of the times and the state of society, and therefore need not be traced to any particular and predominating cause.

The only author who regards the feudal system as absolutely hostile to chivalry, is Pinkerton; but as his opinion is not supported either by authority or argument, it cannot be expected to outweigh the reasons, which have been brought forward to prove that this system, though it did not actually give birth to chivalry, was very instrumental in bringing it to maturity.

Objections to the different theories of chivalry.

To sum up the grand inference from the investigation which has been gone into, and the train of reasoning which has been pursued. The theories respecting the origin of chivalry, which were enumerated in the beginning of this article, evidently confound two things, quite distinct in their nature and character. That theory which would seek the origin of chivalry among the nations of the East, overlooking that nice regard to honour, that courtesy of manners, and that respectful and delicate gallantry, which formed its characteristic features, insists only on that resemblance between the knights of chivalry and the warriors of the East, which consists in their common passion for war, enterprize, and adventure. In this theory, therefore, the natural result of a certain stage of society is confounded with a regular institution, existing certainly in a stage of society nearly similar, and therefore embracing its features, but also superadding many regulations, and exhibiting many points of character, utterly inconsistent with the manners, the feelings, and the institutions of the East.

That theory, which ascribes the origin of chivalry to the Scandinavian nations, approaches nearer the truth. It can trace among them not merely the love of warfare, enterprize, and adventure, and a high estimation of personal valour, but also a nice regard to honour, and a respectful and delicate attention to the female sex. But these qualities existed generally; they were not the peculiar characteristic, nor regarded as the especial obligation of a certain portion of the community. In short, among the Scandinavians, almost every feature that afterwards composed chivalry may be traced; but they were not among them, as when it was established, arranged in their regular order, and with their due proportion.

It only remains to notice the theory, which considers chivalry as of Armorican origin. Among the Celtic tribes, there is no evidence of that high regard to honour, and the female sex, which has been so often stated as the characteristics of chivalry. This theory, therefore, is not built on such strong presumptive evidence as that which refers it to a Scandinavian origin.

Those authors who regard the examples of military investiture, during or before the reign of Charlemagne, as proofs of the existence of chivalry at that early period, likewise confound two things quite distinct in their nature and character. By the military investiture, the right of carrying arms, and engaging in warfare alone, was bestowed; and there does not appear to have been any other obligation imposed, but that of employing the arms, with which the soldier was invested in the service, and for the protection of his sovereign. Although, therefore, the spirit of chivalry was drawn from the love of military enterprize, which is common to all nations at a certain period of their age, and from that nice susceptibility of honour, and high estimation of the female sex, which were peculiar to the Scandinavian tribes; and though the ceremonies of chivalry were borrowed from those employed on occasions of military investiture, yet these facts are by no means sufficient to warrant the conclusion, that it derived its origin from any of these sources.

Origin of chivalry.

Chivalry, properly so called, as has been already observed, cannot be traced further back than the eleventh century. In the beginning of that century, the rudiments of the laws of chivalry may be found in the decisions of the famous Council of Clermont. About the year 1025, several prelates, and particularly the Archbishop of Bourges, drew up a set of laws for the maintenance of order, and the protection of the weak; which were afterwards submitted to, and confirmed by, the Council of Clermont. These laws every person of noble birth, when he had attained the age of twelve years, was obliged to submit himself to, by swearing to their observance before the bishop of his diocese. By the oath which he then took, he bound himself to defend and protect the oppressed, the widows, and orphans; to take under his especial care married and unmarried women of noble birth; and to use his utmost endeavours to render travelling safe, and to destroy tyranny. Hence arose, as Boullainvilliers observes, in his *History of the Ancient Government of France*, the order and the laws of chivalry, and the honour attached to the name of knight. That the laws established by the Council of Clermont formed the rudiments of those laws, to which every person submitted himself when he became a knight, is sufficiently evident from the summary of the latter, which is given in the work entitled, *Ordre de Chevalerie*, as quoted by Monsieur de Sainte Palaye, *Office de chevalier est de maintenir femmes, veuves, et orphelins, et hommes misaisés et non puissans.*

Spain and France appear to have been the countries in which chivalry was first regularly formed into a system, and where it flourished in its greatest splendour, magnificence, and purity. The natural character of the Spanish nation; the necessity in which they were placed of exercising constant activity and enterprize, to secure themselves from their infidel invaders; and the frequent opportunities and occasions for protecting and avenging the weak and defenceless, to which the state of their country for many centuries gave birth; all conspired to the early establishment of chivalry among them. In France, the magnificence in which the barons lived, the pervading influence of the feudal system, which then was on a most sumptuous, extensive, and lasting footing; and the regular institution of schools in the castles of the nobility, for initiating their youth into the rules and practices of chivalry, contributed to the same effect.

Germany, also, was an early seat of chivalry, and produced many knights, who practised it with the greatest zeal, and in its utmost strictness and purity. In England, it was rather of later birth and slower growth; nor till the intercourse between this country and France became familiar and frequent, were the English knights of great celebrity.

Institutions of chivalry.

We shall now proceed to give an account of the institutions of chivalry; of the education by which the young nobility were trained up to the duties and the honours of knighthood; of the degrees through which each candidate for these honours was obliged to pass; of the ceremonies that were employed in making a knight; of the armour which he was allowed or expected to wear; of the rights and privileges with which he was invested; of the duties and virtues which he was called upon to practise; of the feats of arms in which he employed his leisure, and indulged his passion for actual warfare; of his amusements when not thus engaged; of the causes and ceremonies of his degradation from knighthood; of the manner in which his old age, when he was no longer fit for activity and enterprize, was spent; and of the ceremonies and honours attendant on his funeral.

Those extravagancies of chivalry, knight-errantry, and the fraternities or brotherhoods, which proceeded from the passion for adventure and enterprise, and from romantic and fanatical ideas of love and gallantry, will also be noticed and described.

As the character and influence of the female sex were so very prominent and predominating in the age of chivalry, the education which they received, the part which they performed in calling forth and rewarding the virtue of knighthood, and their general manners, habits, and employments, will be cursorily touched upon.

Lastly, the period and causes of the decline and extinction of chivalry, and the impression which it has left on the character of modern times, and on our mode and principles of intercourse with one another, will naturally form the subject of the concluding part of this article.

Education of the young nobility.

Till the age of seven years, children of a royal or noble birth, by a custom which appears to have been followed in the time of the Emperor Julian, and which continued in France till the Revolution, were entirely committed to the management and charge of the women. When they had attained that age, such as were destined for chivalry entered on that course of education, which was to prepare them for the enjoyment of its honours, and the performance of its duties. The scene of this education was either the castle of their father, of some of their relations, or of a neighbouring noble: in most cases the last was preferred, especially if in it were to be found youths of the same age, and preparing for the same object. It was not considered degrading for the most noble youths to receive their education and their maintenance from those who were not related to them: on the contrary, as they necessarily discharged certain offices of the household, in order to prepare themselves for the ranks of knighthood, the obligation was deemed mutual.

The appellation that was given to these youths from the age of seven to that of fourteen, was that of *Pages*, *Varlets*, or *Damoiseaux*: in our old English ballads and romances, *Child* was a common name for them. These appellations, however, were sometimes applied to those who had reached the higher rank of *Esquire*.

The pages were kept in constant and active employment: they waited on the master and mistress of the castle, both at home and abroad; during their journeys, their visits, their walks, and even at the chace, it was the duty of the pages to be in attendance. They even waited at table, and acted in the capacity of cup-bearers. The renowned chevalier Bayard, in his early youth, was placed in the house of his uncle, the Bishop of Grenoble; and, we are told, that when the latter paid a visit to the Duke of Savoy, he was accompanied by Bayard, who attended upon him at dinner.

The first impression that was made on the minds and feelings of the pages, were those of love, gallantry, honour, and bravery. Surrounded by noble ladies and valiant knights, the instructions they received, and the examples that were displayed before them, all had this tendency. Chivalry they were taught to reverence, as containing every thing that was alluring, grand, and desirable: and the only means by which they could gain this object, they easily and early perceived were those of devotion to the female sex, and skill and courage in warfare.

They were taught, at the same time, by the ladies of the castle, the rudiments of religion and of love. *The love of God and of the Ladies* was constantly impressed on their minds:—it was the first lesson they received. In order that they might have opportunities to practise, in some degree, the instructions they received, it was customary for each youth to select some young, accomplished, and virtuous lady; at her feet he displayed all his gallantry; to her he disclosed all his thoughts; her he made the judge of all his actions. She was authorised and called upon by him to polish his manners, and to render him fit for the softer and more elegant duties of chivalry.

The emulation natural to youth; the martial sports and exercises which they daily witnessed; the discourses of war and of feats of arms which they heard from their master and his guests, all conspired to give them a passion for the sterner and more laborious duties of chivalry. The sports in which the pages employed and amused themselves, were of a military nature: unable, from their extreme youth, to hurl the lance, they gradually trained themselves up to that exercise, by throwing the dart; their hoods (*chaperons*) they used as helmets; and, in short, by every method in their power, exhibited and fulfilled their desire of becoming expert warriors.

Degrees through which the candidate for knighthood passed.

In this manner was their time spent, till they reached the age of fourteen years: when they passed from the care of the women into the rank of pages, no ceremony was deemed necessary; but their introduction into the rank of esquire was thought to require some solemnity. Now, for the first time, arms were about to be placed in their hands; they were about to have a foretaste of those honours and dignities, surrounded by which they had passed the last seven years of their life. The ceremonies used at the introduction of the page to the rank of esquire, were very similar to those employed at the military investiture which have already been described, and noticed, as having been confounded with those of perfect chivalry.

As soon as the youth had reached his fourteenth year, he was led to the altar by his father and mother, each carrying a wax taper in their hands. The officiating priest took from the altar a sword and belt, which, having previously bestowed his benediction on them, he fastened to the side of the youth, who, from that moment, was authorised to carry arms.

The esquires, the second degree of rank, consisted of several classes and departments, each of which had their respective duties and employments: there were esquires of the body, who were attached to the person, first of the lady, and afterwards of the lord; esquires of the chamber; esquires of the stable; and carving esquires;—besides these, the inferior departments of the household, such as the wine cellar, and the pantry, had their respective esquires.

The highest rank was that of esquire of the body, who was also called the esquire of honour: he was in constant and close attendance on his master, especially in times of difficulty and peril: he carried his banner when he went into battle, and sounded his *cry at arms*. It was also his office to dress and undress him. As a knight always was attached to some lady, his messages of love and gallantry, and the care of his interest when he was occasionally absent, were committed to this esquire.

But before the youth could expect to attain to this high rank, it was necessary that he should perform many inferior offices, and learn the preliminary and intermediate duties. These consisted in receiving with hospitality, and waiting upon with diligence and zeal, the guests who came to his master's castle;—in listening in silence to the conversation of those who were of superior rank, and in displaying, on all occasions, modesty, diffidence, and attention. The first employment of the esquire seems to have been at the table, where he was expected to display the qualities proper for his station, in the neatness, adroitness, and dispatch with which he cut the meat, and in the ease and elegance with which he served it to the guests.

It was the business of other esquires to arrange the table; to bring in water with which the guests might wash themselves after the repast was over; to take care that every thing was replaced in its proper order and situation; and to arrange the grand hall for the dances and amusements with which the evening generally closed. When bed-time came, some of the esquires accompanied the strangers to their rooms; and according to the evidence of some of the romances, they were even employed to make the beds.

It is plain, from this account of the duties of this class of the esquires, that their rank was not high: how long they continued thus employed is not known; but the next step in dignity was that of squire of the stable. The duties of this office were much more important, and required a considerable degree of skill and experience. As their name implies, they had the care of the horses; with the assistance of inferior esquires, they trained them up to war, and taught them all the paces and movements that were necessary in tournaments or in battle; they also kept their master's arms constantly clean and ready for use.

But it was when their master prepared to go forth arrayed for battle, or for feats of arms, that the esquires were all in active employment: while one held the stirrup as he was mounting his horse, others brought him the different parts of his armour, and his pennon or banner. As it was not customary for a knight to ride on his war-horse, except when an enemy was in sight, or in actual battle, one of his esquires led it by his side, and gave it him when requisite; another generally preceded him, mounted on a common horse, carrying his shield and his helmet on the pommel of his saddle. Whenever it was necessary that the knight should mount his war-horse, and equip himself in full armour, each esquire performed his allotted duty in fitting on, with skill and expedition, the different parts. When the knight entered a church or any holy place, he took off his helmet and his sword, and gave them into the hands of the esquire of honour.

In the time of battle or of single combat, it was the duty of this esquire to watch all the movements of his master, in order that he might profit by what he saw, and that he might be ready to give him fresh arms or a fresh horse if he required it. It was also lawful for the esquire to ward off the blows that were aimed at him; to point out how he might attack or defend himself with success and advantage; and, if victorious, how he might render his victory complete. The knights, likewise, gave the prisoners whom they took in battle into the custody of their esquires.

The watchfulness and precaution so necessary in the feudal times, were carefully and early taught the esquires; the castles which they inhabited were guarded by them in all their different parts: they were stationed on the towers, in order to give the alarm in case of the approach of an enemy; and they regularly traversed and examined all the chambers and courts.

Thus the time of the esquire was spent, from the age of fourteen to that of twenty-one; for it was not, in general, till the latter period, that he was admitted to the full honours of chivalry. The cases in which this regulation, with respect to age, were dispensed with, were where the youths were of royal blood, or where their merit was very conspicuous and pre-eminent. There are examples of esquires having been made knights at the age of sixteen, fifteen, and fourteen; but even in cases of noble birth, fifteen seems to have been the earliest legitimate age, since the sovereign could not levy the *aids of chivalry*, for the purpose of defraying the expense of making his son a knight, till that son had attained this age.*

Every person who was a knight could confer the honours of knighthood. Some authors maintain, that prelates and ladies had also the privilege of knighting, but this opinion is unfounded. It has been already noticed, that military investiture was originally conferred in England and on the continent by the hands of the priests; and this ceremony having been confounded with that of knighthood, has given rise to this idea. In the same manner, the initiation of the page into the rank of esquire, admitting of the presence and participation either of his father or his mother, it has been erroneously supposed that ladies could confer knighthood. There is, however, one instance of knighthood having been conferred by a lady, though, from the singularity of the circumstance, it must be regarded as of doubtful authority. Menard, in his *Life of the Constable Du Guesclin*, relates, that his widow girt Andrew de la Val, afterwards Marshal of France, with the sword of her husband, and *made him a knight*.

Whoever appeared to receive the honours of knighthood, was to be of conspicuous merit, of sufficient estate to support the dignity, and, according to the regulations of chivalry in Germany, of three noble descents by the father's side.† No person who was lame, or who laboured under any disorder which disqualified him for warfare, however rich or noble he might be, could be made a knight.

Such were the general regulations with respect to those whom it was lawful to admit to the full honours of chivalry; but there were exceptions. Monsieur de Querlon, in his *Memoire sur la Chanson*, gives many instances of trombadours, who followed their masters to the wars, having been knighted; and we have the testimony of Glanville, that in England, during the reign of Henry II. enfranchised villains, born in servitude, were sometimes knighted.

Esquires were raised to the rank of knights either in time of peace or war; the ceremonies usual during the latter were comparatively simple and short; those employed in times of peace were minute, solemn, splendid, and magnificent. The occasions on which knighthood was most commonly conferred, during peace, were the high feasts of the church, especially Pentecost; the proclaiming of peace, or a truce; the coronation of kings; the birth and baptisms of the royal family; the days when princes themselves were made knights; on their marriages; and at tournaments.

Ceremonies employed in making a knight.

The esquire prepared himself for the honour he was about to receive, by rigid fasting, and passing the night in prayers, along with the priest and his sponsors, in a church, where his arms were hung up. As a type of the purity of manners which would be required of him, he clothed himself in white, after having performed his ablutions in a bath. A full and solemn confession of his sins, a serious attention to a discourse, in which the duties of chivalry, and the articles of his religious faith, were detailed and enforced, completed the preliminary part of the ceremony. When this was performed, he again entered the church with his sword slung on his shoulder; taking it off, he presented it to the priest, who consecrated it, and returned it to him; immediately after this the novice received the communion; then with clasped hands he threw himself on his knees before the person, who was to confer the honour of knighthood, and delivered him his sword. A number of questions were put to him: he was asked, What were his views and motives in entering on the order of chivalry? Whether he had any object but the maintenance of its honour, and the support of religion? If his replies were satisfactory, the efficient and final ceremonies began. The novice received from the hands of the knights—sometimes from those of the ladies—all the insignia of chivalry. One approached him, and put on his spurs; in ancient times putting on the left spur first; afterwards the custom was changed, and the right spur was put on first. After his spurs were put on, another knight or lady clothed him in his coat of mail, his cuirass, and the other parts of his armour. The last thing that was given him, was his sword; this was deemed the most essential part of the ceremony. He was *dubbed* (*adoubé*)‡ in this manner, still continuing on his knees. The person who confirmed the order, then rose from his seat, approached the novice, and bestowed on him the *accolade*; this consisted, generally, of three blows with the flat side of the naked sword on the shoulder, or on the neck of the novice; sometimes it was bestowed by a blow with the palm of the hand on the cheek. The meaning of the *accolade* has been differently interpreted; some regard it "as an emblem of the last affront which it was lawful for him to endure;" others as borrowed from the mode which the Romans practised, when they manumitted their slaves; and others as a warning of the difficulties and dangers, to which, in the discharge of the duties he had undertaken, he would necessarily be exposed. When the *accolade* was bestowed, the person conferring the order pronounced him a knight in the name of God, of St George, and of St Michael the archangel; sometimes counselling him to be brave, undaunted, and loyal. When he leaves the church, or the place where the ceremony has been performed, a horse is brought him, which he mounts, and with drawn sword and brandished lance, exhibits himself fully equipped, in the most frequented and public part of the village. As soon as he is recognised by the populace, they shout and dance around him, thus proclaiming their joy at having acquired a new protector. When several were made knights at the same time, it was usual for them to make their horses prance, and wheel in *time* with the dances of the populace. This M. de St Palaye supposes to have been the origin of the *fetes* or *ballets à cheval*, which were common at the French court, even in the time of Brantome.§

There was some variation in these ceremonies at different periods, and in different countries. On occasions of simple military investiture, and probably also in the ruder ages of chivalry, the person who officiated kissed the new knight on the left cheek, when he gave him the belt; this was called the kiss of peace. Afterwards, an embrace was given instead of the kiss; and from this circumstance, the term *accolade* is evidently borrowed. In Spain, the kiss and blow were sometimes given, with these words, "Awake, and sleep not in affairs of knighthood," or, "God assist you in the performance of your promise." Sometimes, out of honour to the person knighted, as in the case of the Cid, the blow was omitted; and sometimes the blow only was given. In time of war and actual service, the occasions and opportunities for conferring the order of chivalry were very frequent and numerous. When the army entered on hostile territory, during their march, and even sometimes during their retreat; when it was necessary to force the passage of a river or bridge, before an assault or battle, and at their termination, the honour of knighthood was conferred on many esquires. It was a point much discussed among knights, and in books of chivalry, whether it was more proper and more honourable to confer knighthood before battle or after it: if it were conferred before battle, it served to rouse and animate the courage of the new knight, who was always placed in the front rank, or in the post of danger, and who considered himself bound to prove that he was worthy of the promotion that he had received. But as it happened, sometimes, that the battle, on the supposed eve of which the knights were made, did not take place, the honour was conferred on those, who neither had distinguished themselves, nor had an opportunity of doing so.* Brantome therefore, and other valiant and experienced chevaliers, were of opinion, that the honour should be conferred after the battle, when the esquire had shewn himself worthy of obtaining it, and when no circumstance could take place, which could make him be regarded by his fellow knights as a person of untried valour and merit.

---

* There were four cases, in which a sovereign or knight could raise the *aids of chivalry* on his subjects or vassals; that mentioned in the text, the marriage of his daughters, the payment of his own ransom, and the expense of any enterprise beyond sea.

† By an old law of France, if any man, not noble by his father, though he was by his mother's side, had been made a knight, he might be degraded, by having his spurs cut off on a dunghill. (Selden's *Titles of Honour*, Part II. c. iii.)

It would appear, from a passage in Froissart, where he mentions the knights that were made by the King of England in 1359, at the attack on the palisades of Paris, that a helmet was a necessary piece of armour in the creating of a knight, since the King, who wished to include his esquire of honour in the promotion, could not do it, because the esquire could not find his helmet.

‡ This word is evidently derived from the Teutonic *doopen*, to dip, and must have been borrowed from the ceremony of bathing.

§ The rejoicings and amusements, which took place when the order of chivalry was conferred, and which, in the old historians, are denominated *festum tyrocinii*, lasted many days; where the person admitted was of high rank, tournaments were held.

The ceremony during war, was very short and simple; the person to be knighted, presented his sword to the person who was to bestow the honour, who returned it to him, giving him at the same time the accolade. Although this was esteemed the most honourable knighthood, yet it is doubtful, whether the rights and privileges conferred, were not merely personal; and it is certain, that no obligation to take the oath was imposed or necessarily implied.

When the honour of knighthood was bestowed by a sovereign, or noble of high rank and great wealth, it was always accompanied with valuable presents; and in every case, robes of great splendour were bestowed on the new chevalier. When it happened, that he had not fortune adequate to the proper support of his dignity, the sovereign assigned him a sufficient revenue of money or lands.

Equipments of the knights.

Horses.

The most important part of the equipments of the knight, was his horse: of this animal he had different kinds; the great horse, or war horse, was employed only in actual battle or in feats of arms.† As the knight, when fully equipped, was a great weight, it was necessary that this kind of horse should be very strong. All horses which exceeded the size of six hands and four fingers were deemed *great* or *war* horses. These horses were caparisoned with great splendour, and ornamented with housing and saddle cloths, embroidered with different colours, and exhibiting the coat of arms and the *tincture* of their riders. In the time of Henry I. the war horses appear not to have been protected with any armour; but in the reign of Richard I., and subsequently, they were covered with a coat of mail, interwoven with iron rings, sewed together with thread; these horses, when so armed, were called *barded* horses. As it was against the laws of chivalry to strike a horse at a tournament, the war horses, on these occasions, were covered only with silk or velvet *bards*, embroidered with armorial bearings. Sometimes, also, in tournaments, and even when travelling on his palfrey, the knight ornamented the crupper and other parts of the harness with little bells. The common gait of horses, used in tilting, was that called *ambling*, and they were taught this action by the shoes on the hinder feet having a long point projecting from the toe. Besides the great horse, the chevalier had his palfrey, his courser, and his bat horse. The palfrey, as has been already stated, he rode on, while proceeding to the battle or tournament; the courser was employed, where expedition was required, either in affairs of gallantry, or war; and his bat horse was designed for carrying such of his arms as were not committed to the charge of his esquire: these generally consisted of a second lance, shield, &c. in case of accident; the bat horse also carried what little baggage the knight took with him, and was occasionally mounted by one of the esquires.

Arms.

It was deemed dishonourable for a knight to ride on a work horse, or a mare; and one mode of degrading him was to deprive him of his war horse, and oblige him to ride on a work horse; no other knight would tilt with, or even address one so mounted. A knight was also dishonoured by being seen riding in any carriage drawn by these common horses. In the days of chivalry, the horses that were rode by knights, whether war horses, palfreys, or coursers, were all *entire*. The offensive arms of the knight consisted of a lance, sword, dagger, battle axe, and maces of different kinds; sometimes he fought with heavy clubs of iron; but the *lance* was his distinguishing weapon; it was longer than the lance now in use, and resembled that of the Polish cavalry. It was strong and difficult to be broken, and commonly made of the lime, aspen, or ash: the last kind of wood was preferred. The lances that were used in tilting, had blunt heads, or with a *coronel* on them: the staves were thick at the but end, near which they had a cavity for the hand; at the point a *banderolle* or *pennon* was fixed. Originally the shaft was plain, but afterwards fluted. As in tilting the knights sometimes dismounted and fought on foot, in these cases, they broke the shaft of their lances, in order that, by shortening it, they might have more command over it, in thrusting at their adversary. The sword used by the knights of Germany was longer than that generally used by the knights of France; and the former country, in the time of Joinville, was famous for this weapon. There was a particular kind of sword called *braquemart*, that was short, strong, and blunt at the point. In the reign of Saint Louis, King of France, the point was sharpened. The handle of the sword was in the form of a cross, and the name of Jesus was frequently inscribed on this part of it, so that when a knight swore by his sword, his usual oath, he swore by his religion, as well as by his valour. The dagger worn by a knight, called by the French writers *misericorde*, or the poignard of mercy, was used only in close and desperate struggles, when the combatants, unhorsed, and so near to each other, that they could not use their other weapons, were obliged to have recourse to these. It was also employed to dispatch the vanquished knight, unless he cried for mercy. It was commonly worn in the bosom.

---

* Tillet relates, that at Kioufosse, in 1339, when the hostile armies were drawn up, several knights were made, in expectation of instant battle. The battle, however, did not take place; and a hare running along the line, during the ceremony, the new made knights, were called, in derision, *Knights of the Hare.* (Tillet, quoted by St Palaye, I 253.)

† This kind of horse is called by the Latin writers, *dextrarius*; by the French, *destrier*. It is generally supposed, that it took this name from the circumstance of its having been well trained for the purposes of war and chivalry, by the hand, (*dextra*). But St Palaye is disposed to derive the appellation from another cause. When the knight was not in actual battle or combat, he was mounted on his palfrey, while his esquire led his war horse in his *right* hand.

Armour.

The principal parts of his defensive armour were the helmet and bacinet, the coats of mail of different kinds, and the shield. The helmet was made with holes for breathing and seeing; and it was of the utmost importance, that the esquire should take care that the rivetting of the top of the cuirass, and of the helmet, should be firmly done, before a battle or tournament, since otherwise it might happen, that, by a violent blow, the helmet might be turned with the wrong side foremost. This happened to a French chevalier at the battle of Bouines; and the fatal accident which deprived Henry II. of his life, is supposed to have originated from some negligence in this respect. The crest of the helmet, called by the knights of romance *le plus haut de ses biens*, was ornamented with *lambrequins*, the favours which their mistresses had bestowed on them, and frequently with the images of some fancied monster. The bacinet was a light kind of helmet, so called from its resemblance to a *bason*; this the knight, when fatigued, put on instead of his helmet. Sometimes a kind of cap was fastened to the lower part of the crest of the helmet with ribbands; this cap was composed of thin plates of iron, and was put on, when the knight took off his helmet for the purpose of breathing more freely; in this case, the ribbands which had fastened it to the crest, flowed down on his shoulders, whence they had the name of *volets*.

Coats of mail consisted either of chain or plate armour; the latter were more ancient and more common, having been used in France very early in the days of chivalry. The haubert, haubergeon, or hauberk, as it was indiscriminately called,* was composed of double plates, or scollops of steel, impenetrable to any arrow or lance. It covered the body completely from head to foot. This kind of defensive armour was allowed only to the knights. The hauberk of the simple esquire was distinguished, by its being without hood and hose. The cuirass, which came into use long after the coat of mail, consisted of two parts: a back and a breast piece of iron, fastened with straps, and covering the body completely before and behind; it was much more heavy and cumbersome than the coat of mail. It was reckoned as dishonourable for a knight to quit his cuirass or coat of mail, as for a Greek or Roman to lose their shield. Of the shield it it is not necessary to give any description.

The armour which was used in tournaments, was much lighter, and more ornamented than that employed in battle: "The helmet was perforated only on the right side; the left side of the face, and the left shoulder and breast, were covered with a plate called a grand guard, which was fastened on at the stomach. On each shoulder was also fixed a plate, declining from the face like wings, in order to protect the eyes from the point of the lance: these were called *pass-guards*. From the right side of the cuirass a moveable bracket projected, called the *rest*, for the purpose of supporting the lance." Grose on *Ancient Armour*.

Privileges of the knights.

One of the first privileges which the knight received was, that of bearing a coat of arms. Coats of arms, in a more loose and extended sense, are very ancient; they are assigned by Eschylus to the warriors against Thebes; but these were of a very different kind, and destined for a very different purpose. The coats of arms used in chivalry were fixed and certain; their purpose to distinguish families. The coats of arms mentioned by Eschylus were frequently changed, and, indeed, were merely temporary, being used only in battle to distinguish friends from foes. There is much difference of opinion respecting the time when armorial bearings, properly so called, were first used. The circumstance of their not appearing on seals till about the eleventh century, has induced many authors to fix their introduction at that period. But the fact will by no means bear out the inference; besides, that if we may credit Uredius, in his Treatise on the Seals of the Counts of Flanders, a coat of arms is to be seen on the seal of Arnulphus, the great Earl of Flanders, in the year 941. But the mode in which figures on seals were for a long time represented, prevented the coat of arms from being seen; as the horseman, on the more ancient seals, appears riding towards the sinister side of the seal, commonly bearing on his left arm a shield cast back in such a manner, that the concave side alone is visible. Now, for a long time the upper side was the only part where the coat of arms was painted. That this is the cause why armorial bearings are not visible on ancient seals, is evident from this circumstance:—that as soon as the position of the horseman on the seal was changed, they became apparent. The fashion altered soon after the reign of Henry I. The most ancient English seal, with arms on it, is that of Richard I.

But to return from this digression. The sovereign or noble who bestowed the honour of knighthood, encouraged or permitted the newly made knight to assume the whole or part of his arms; sometimes, but very seldom, he assumed the entire armorial bearings; more frequently, he incorporated part of them with his own coat of arms. He in his turn transmitted the whole, or part of his armorial bearings, to the knights whom he created; whence the resemblance in different parts of the coats of arms of families not allied, which existed in the days of chivalry.

Many knights, however, refused to assume any armorial bearings, till they had won them by their merit or their valour; or, if their shield was adorned with the armorial bearings of their family, they carefully and modestly covered it over, till they had acquired celebrity in war or tournaments. It not unfrequently happened, that the strokes of the sword or the lance cut off the covering from their shields, and displayed at once the family and the merit of the newly made chevalier. Sometimes he exhibited a shield painted white, or of any other uniform colour throughout, and anxiously waited till an opportunity of displaying his valour might give him a right to inscribe armorial bearings on it. If he was so unfortunate as to be defeated in combat or in battle before he had assumed his coat of arms, he preferred death to the disgrace of making himself known. In the romances there are many examples of this sort; and that the authors of these romances copied from the actual practice of chevaliers, appears from the undoubted testimony of a chronicler quoted by St Palaye.†

The new made knight generally carried a white shield,

Chivalry.
Privileges of the knights.

unadorned with armorial bearings, for the space of a year, unless some opportunity occurred before that period of signalizing himself in battle. If he had fought against the Infidels, he assumed a cross as part of his arms; if he excelled in the management of the lance or the sword, he added these; had he forced a barrier or a castle, these also were assumed; and in several instances, the wounds which he had received, were pictured in different modes on his blasonry. The head of the lance was very commonly adopted; and from this circumstance, according to St Palaye, the fleur-de-lys of France takes its origin.[*]

Another privilege bestowed by chivalry, immediately connected with, and indeed necessarily resulting from, that of armorial bearings, consisted in the new knight being authorised to make use of a seal. A passage is quoted by Selden from an old chronicle, in which it is expressly stated that Richard, Earl of Chester, in the reign of Henry I., when he conveyed his lands in Weymonsley to the Abbey of Abingdon, made use of his mother's seal, because he had not yet arrived at the honour of knighthood, (*nondum enim militare balthio cinctus erat,*) and St Palaye and Boullainvilliers (*Histoire de l'Ancien Gouvernment de France,* i. 326,) maintain the same opinion. Yet that in England, seals might be used even by inferior persons, appears from a passage from Ingulphus, quoted by Selden, and another from Glanville, given by the same author. Du Tillet also cites a judgment as old as the year 1366, in which an esquire is said to *change his seal* when he attains the rank of knight.

It is probable, however, that to wear seals with armorial bearings on them, was the exclusive privilege of a knight; and that the seals mentioned by Ingulphus and Glanville, and the judgment cited by Du Tillet, refer to seals without armorial bearings; since it is undoubted, that esquires, and men of inferior birth, were not permitted the use of coats of arms. A knight, beside a large seal which he employed on grand and important occasions, had generally one or more seal-rings on his finger; and the possession of these was deemed so sure a mark of his delegated authority, that his vassals yielded implicit obedience to whoever displayed them.[†]

The knight was also privileged in the dress he wore, and in the ornaments by which it was distinguished. On the day of his knighthood, he received from his sovereign a splendid mantle, which completely covered his person, and swept the ground with a long train. This, which was called the king's livery, and which was renewed regularly twice a year in winter and summer, as well as at grand feats or tournaments, was lined with the most costly furs, and adorned with gold. No person of rank inferior to that of a knight, durst presume to wear gold, fur, or silk. Gold, as the most precious metal, was reserved for their use: it formed or covered their spurs, and adorned the trappings of their horses, as well as their own robes. If the chevalier appeared in the rich and splendid silk of Damascus, the esquire was clothed in satin; and if the latter was dressed in the silk of Damascus, the chevalier was clothed in velvet. Scarlet, or some other colour partaking of red, was appropriated to the knight, and no inferior person durst presume to appear in any colour at all resembling it.[‡]

But the knight possessed rights and privileges of a higher nature, and more dignified importance. Such was the estimation in which knighthood was held, that for a long time no sovereign could be crowned till he had been knighted; and the son of a king was scarcely permitted to approach the person of his father, certainly not to sit down to table with him, previous to his being invested with the order of chivalry. Birth, however illustrious and noble, bestowed no personal rank, till to it had been added the title of knight. While the rank was only that of esquire, even the son of a king was considered as the servant of the knight in whose family he resided; and, till he became an esquire, he was looked upon as belonging entirely to the women. But, when made a knight, though under the legal age, his knighthood conferred upon him the right of holding his lands, and of rendering homage for them in person; for he was then considered as *emancipated,* and admitted to the full privileges of nobility.

In many cases he was exempt from taxes; and even his servants, and all who were attached to his household, shared in some degree in the same privilege. Neither his horse nor his armour could be seized for debt, although the crown were the creditor. If he came into a court of justice as a complainant, and gained his suit, fines beyond the usual proportion were awarded him; and he could not himself be summoned to appear, without the observance of particular forms, all of which were intended to shew respect to his rank. He was empowered to act in the capacity of a magistrate; and was frequently called upon by his sovereign for his advice as a counsellor, as well as for his assistance as a warrior. When ambassadors were to be sent on any special and important mission, they were always chosen from among the clergy or the knights.

If he chanced to be taken in war, he was seldom confined in prison, and never put in fetters; his word was generally deemed sufficient security. When he was confined, a particular kind of prison was allotted him, called the prison of courtesy, (*courtoise,*) where he experienced the most delicate and respectful attention, and received every indulgence, consistent with his situation, that could soften the rigours of his captivity, and soothe the anguish he experienced on account of his ill fortune. He was at liberty to offer his services to a foreign power, when his own sovereign did not require them. When he travelled, either for the purposes of engaging in battle or tournament, himself and all his train were received and hospitably entertained at the castle of every knight which lay in his way.

The outward appearance and internal decorations of his castle bespoke his rank. The *crennels* and towers which were intended for their defence, marked also

---

[*] Pinkerton, in his notes to Barbour's *Bruce,* i. 47, says, that the fleur-de-lys was only known in the time of Philip the Hardy, king of France, A. D. 1270, and was taken from the gold coins of Florence with that flower; but, according to Ruddiman, (*Introduction to Anderson's Diplomata,* 114,) Louis VII., surnamed the Younger, in 1136, first used the lily, but only a single one. Some suppose, that the tressure of Scotland was borrowed from the arms of France, in consequence and in token of the amity between the two kingdoms; but it is more probable that, in both instances, the arms were originally the head of lances, and were adopted in conformity to the custom mentioned in the text.

[†] For a striking instance of this, see *St Palaye,* i. 353. This author also cites and corrects a passage from an ancient Fabliau, which points out the armorial shield and the seal as peculiar and privileged marks of a chevalier.

[‡] St Palaye offers a derivation of the word *rogue,* which has puzzled etymologists, at least plausible and ingenious. From the circumstance of the red (rouge) colour being appropriated to men of rank and power, the word *rouge* acquired the meaning of proud and arrogant; and, by a transposition of the letters, by no means unlikely or uncommon, this author supposes the word *rogue* was formed. (i. 345.)

Privileges of the knights.

the dignities and honours of the owner. On the highest summit of them, a vane, or pennon, or a helmet was fixed, which served as a signal of courteous and welcome hospitality to all of the same order, who were journeying that way on affairs of gallantry or war. Every apartment of his castle, and the furniture with which it was embellished, and the whole domestic economy and arrangement also, were marked by the peculiar privileges and honours of knighthood.

While, however, the knight possessed these privileges and rights, and was authorised to exercise over the esquires and pages of his household supreme authority, he was deemed answerable for the faults they might commit, and every infraction of the laws of chivalry or injustice of which they might be guilty. If his armorial bearing, the symbol and proof of his rank, opened for him a passage through every fortified place, and admitted him to the palaces of sovereigns, where he was received with the utmost hospitality, and when he departed loaded with costly presents, and even supplied with money to defray the expences of his journey; he was on his part expected not only to demean himself with the utmost courtesy, but to maintain such good discipline among his esquires, pages, and other attendants, that there might be no room to complain against them. He was obliged to recompence by every means in his power, or which were required of him, every act of injustice or violence which they committed. The law fined, or punished with infamy, all who detained strayed hawks, hunting dogs, or horses; and if these were found in the possession of any of the family of a knight, not only the guilty person, but the knight himself, payed the fine, and was exposed to the infamy of the punishment. So complete and unrestricted was his authority over all who inhabited his castle, that nothing was supposed to be done without his orders, permission, or knowledge.

The institutions and laws of chivalry were so careful to mark out the knight, that the line of distinction between him and the esquire was drawn with great minuteness and particularity. This has been already partly noticed in describing the armour, the dress, and the privileges of the knight; but there are a few other particulars which we shall now point out. A shield and sword were the only weapons allowed the esquire; and he was not permitted, nor with this imperfect armour would it have been prudent, for him to engage in combat with a knight.* He was also debarred from engaging in tournaments, at least on the most solemn day, and on high occasions. While the spurs of the chevalier were gilt, those of the esquire were only silvered. The hair on the forehead of the former was carefully kept cut short, probably in order that no advantage might otherwise be taken of him in combat; the hair of the latter was not thus distinguished. It would appear, also, from two passages quoted by St Palaye, (i. 329.), from William of Tudela, that the horses of the chevaliers and the esquires were distinguished, by the former neither having their hair cut off or concealed by the armour; while the latter were unarmed, and with their hair in its natural state. It is probable that the hair of the chevaliers horses were cut off, in order that the armour might sit more closely and easily.

Besides awarding to the knight double the sum when he came into a court of law, which, under the same circumstances, would have been awarded to an esquire;—the former, when he received presents from his sovereign, or any noble, had always double in value to the latter. After a battle, when the booty was to be divided, the gold, silver, the war-horses, and the palfreys, belonged to the knights of the army; the rest were given to the esquires. In the plunder of a country, it was deemed below the dignity of the former to take any of the sheep or cattle for their share;—the ransom of a knight, also, was double that of an esquire. While the esquires and pages were obliged to perform military *watch*, this duty was dispensed with on the part of the knights. The appellations of themselves and their wives were also kept carefully distinct; while the titles of Don, Sire, Messire, Monseigneur, (for we must be indebted to the French language for the several terms), were given to the chevaliers, and those of Dame or Madame to their ladies. The titles of Monsieur, or Damoiseau, were given to the esquires, and to their wives that of Demoiselle. In short, the coat of arms, the grand symbol of chivalry, not only brought along with it many privileges, but also drew a broad and marked line of distinction betwixt all who wore it, and those who had not attained that honour.

Privileges of knight-bannerets.

Each knight was expected to bring into the field with him, his esquire, his archers, and men at arms, and four, five, or six soldiers. This was reckoned the furniture of a complete lance: but if he could bring fifty men at arms, or at least twenty-four, each with one or more serjeants, he might be admitted to the dignity of a knight *banneret*. This dignity does not appear to have been known in France before the reign of Philip Augustus; nor does it occur in English history before the reign of Edward I. The knight-banneret was distinguished by his *banner*, which was a flag of a square or oblong form, while the pennon was rounded at the end, and the guidon was nearly of a similar form. A knight-banneret could only be made by the king on the field of battle; the person for whom this honour was intended, was led between two senior knights, with trumpets sounding before them, the heralds carrying his pennon with his coat of arms;—when he reached the tent of the king, the latter took the pennon, and tearing off the top of it, converted it into a banner, and restored it to its owner. The knight banneret had some privileges which distinguished him from the simple knights: he had his peculiar cry at arms, the presents bestowed upon him were double in value to those given to the knight, and he could aspire to, and obtain, the titles of Count, Baron, Marquis, and Duke. As his standard on the field of battle was a banner of a square form, so also that which he displayed on the summit of his castle was of the same shape. Knights, unable to maintain men at arms, thought it no disgrace to fight under his banner.

In Spain, there seems to have been other distinctions; for we are informed that Count Raymond Berenpier, of Barcelona, divided the knights of his court into two classes; the highest were called *Miles vero*. On the day on which a knight of this class was made, he appointed a gentleman to hold in feu under him, and another to bear his shield and lance. The other class consisted of knights minor, who followed the art of minor chivalry without the order.

In the court of a sovereign, where there were many knights, a master was appointed over them, whose authority was very great and extensive: he carried the king's standard—judged all knights in cases of selling or pawning their horses or arms,—and settled all disputes about debts—he had power to expel, but not to adjudge to loss of limb or to death. It was his duty to see that the knights behaved to each other with friendship, courtesy, and decorum; and to maintain among them perfect order and good discipline.

---

* *If, however, a knight acted with unauthorised violence, or unjustly, towards an esquire, the laws of chivalry ordered, that he should fight him on foot, armed like him only, with a sword and shield.*

Duties and virtues which the knights were called to exercise.

"The virtues and endowments that were necessary to form an accomplished knight in the flourishing times of chivalry, were such as these:—beauty, strength, and agility of body; great dexterity in dancing, wrestling, hunting, hawking, riding, tilting, and every other manly exercise; the virtues of piety, chastity, modesty, courtesy, loyalty, liberality, sobriety; and, above all, an inviolable attachment to truth, and an invincible courage." Henry's *Hist. of Engl.* book. iii. ch. 7.

Regard to truth.

The oath taken by the knight consisted of twenty-six articles; and no point, next to courage, was more insisted upon, than a regard to truth. He was even expected to relate the whole truth, when, by this means, he might expose his own misfortune or cowardice in combat. On his return from any expedition or enterprise on which he might have been engaged, he was bound to give in a full and minute account of all his adventures, honourable or dishonourable, fortunate or unfortunate, that they might be registered by the heralds, and cited to animate or to console his companions. No disgrace was reckoned so indelible as that which was received by the imputation of falsehood, or by doubting the word of a knight. Such firm reliance was placed on what he promised, that if taken prisoner, he was permitted frequently to go at liberty, on the condition that he returned and surrendered himself on the appointed day. The most solemn oath that a sovereign could take, was on his character, and on the word of a knight.

Gallantry.

But his love of truth, however great and predominating, was in some cases not equivalent to the power and influence of gallantry. A Provençal poet, who gives a chevalier instructions in the art of love, expressly tells him to prefer his mistress's favour to his regard for truth, where, by expressing that truth, he might injure her character, or weaken her passion for him. His gallantry was even to lead him to disbelieve the evidence of his own senses, if they informed him that his mistress had given him just reason to be jealous. Gallantry, indeed, as has been already observed, entered into the earliest lessons, impressions, and habits, of a chevalier. No motive or command, not even the safety of his country, the preservation of his own life, or the orders of his sovereign, could animate him to such exertions, and to such display of valour, as the hope and desire of obtaining the favour of his mistress, and the determination to render her fame and beauty known and acknowledged throughout Christendom. His highest and most valued title was that of the Servant of Love; the portrait, the device, the livery, or even the most trifling gift of his mistress, was received and cherished with the utmost fondness and reverence: the sight of these roused and preserved alive his resolution and courage in the midst of the greatest dangers and perils. He thought he established the superior and unparalleled beauty of his mistress, if he excelled his companions in feats of arms: when he challenged them to single combat, it was in the name of his mistress; when the sovereign or general led his army to the attack, "Let every one think on his mistress," was the usual and the never-failing injunction. The approbation of his commander or his comrades was but a secondary consideration—the source of inferior joy. *Ah! si ma Dame me voyoit*, was the exclamation of the knight when performing a feat of valour.

Nor was it only in the time of war that the spirit and influence of gallantry pervaded the mind and the actions of the chevalier:—in times of peace, he either devoted himself entirely to the enjoyment of her presence; or, what was more congenial to his taste, and a more certain mode of obtaining her favour, he went from court to court, from tournament to tournament, proclaiming her superior beauty, and challenging the proof of his assertion by all kinds of feats of arms.

Such was the usual character and effects of the gallantry of the age of chivalry; but many knights carried it to a most extravagant length: forming to themselves most fantastical ideas of love, and creating the image of a female perfect in beauty and in virtue, they became enamoured of the offspring of their own imagination. Others less spiritualized, but scarcely less absurd, proclaimed their love for ladies, whom they had never seen, but only read or heard of.

As the laws of chivalry forbade a knight to speak ill of the ladies, or tamely to hear them spoken ill of, it became his duty to warn them from the commission of every thing, that might lower them in his opinion: strictly decorous and respectful in his behaviour towards them, he expected that they should never forfeit their claim to such behaviour. If, however, they transgressed the laws of modesty or prudence, the knight did not fail to stigmatize their failings or their vices in the most public and severe manner; if he passed the castle of one of this character, he marked, in such a manner as could not be mistaken, the dwelling of a lady, unfit to receive a true chevalier. Even at the great feasts or the tournaments, if he perceived those of bad or suspicious character mixed with such as were honourable and virtuous, he immediately led the latter to the more honourable seat; and by this indirect reproof, or by less ambiguous means, brought the blush of shame on the countenances of the former.

Hospitality.

The hospitality of chivalry has already been incidentally noticed, when we treated on the insignia of rank that were placed on the summit of the castles of the knights; these insignia, however, were not deemed sufficient proofs, that the dwelling belonged to a chevalier, ready and desirous to entertain all his brethren, who chanced to travel that way. Every true and loyal knight was also expected to have the door of his castle constantly open: if it were found shut, his character for hospitality, and therefore for true knighthood, was stained. As soon as a knight entered the castle of another, he considered himself, and he was treated, as if he were at home; every thing that could minister to his comfort and his luxury was at his command. So much a part of the regular domestic economy was the reception and entertainment of strangers, that, let their number be ever so great, and their coming be ever so sudden and unexpected, they found every thing prepared for them.

Humanity.

Closely allied to the gallantry and hospitality of chivalry, were its humanity and courtesy: to the vanquished foe, these were exhibited with the greatest care, and with the most scrupulous and delicate attention. Nothing that could wound his feelings, or call to mind his misfortunes, was uttered before him, or brought into his presence. He was treated rather like the conqueror than the vanquished. The courtesy of knighthood even extended to inferiors: the Chevalier De la Tour, in his *Instructions to his Daughters*, quoted by St Palaye, (i. 48.), expressly recommends to them the display of an equal degree of courtesy to those of an inferior and of the highest rank; and quotes the example and the reply of a lady of high quality, who, when she was asked, why she returned the salute of a mechanic, answered, that she should have been more ashamed to have failed in courtesy towards him, than towards a person of noble birth and profession.

Gratitude.

Gratitude also was among the distinguishing virtues of a true chevalier: if in his travels he received the rights of hospitality, or the smallest favour or assistance from a person of the lowest rank, he never forgot it; he declared himself the chevalier of his benefactor, and made a solemn vow to forego the rewards of the most splendid achievements, if they were irreconcileable with his duty to succour or protect him.

Exercises of the knight.

The most noble and favourite amusement and exercise of a knight consisted in justs and tournaments; a rude and irregular species of the latter existed among the Germans in the time of Tacitus, and may indeed be traced among all savage nations that are fond of war; but the just, distinguished from the tournament, as exhibiting the combat of one against one, and the tournament itself, with its regulated pomp and solemnity of preparation and attendance, were unknown before the middle of the eleventh century.

Tournaments.

At first every knight of sufficient importance and wealth proclaimed and celebrated tournaments; but afterwards the sovereign alone exercised this privilege; and none could hold them without his licence and permission. The most frequent occasions, or at least the most splendid, when tournaments were celebrated, were at coronations, royal marriages, or splendid victories. A herald was sent to the neighbouring princes, to proclaim the approaching tournament, and to invite all whose knighthood was unstained to witness, or assist at them. The invitation was eagerly accepted; and a zealous knight did not hesitate to travel to a very great distance to be present at them.

By the laws for their regulation, which were framed by the emperor Henry the Fowler; only persons of armoria lbearings, and who could prove four descents, were admitted to them; if any came, with unfounded pretensions to these, they were excluded and punished: all criminals, also degraded knights, and especially those who had defamed the character of the ladies, were forbidden to attend them. Every knight was to appear in armour, with his armorial bearings on his shield and surcoat: his horse also was to be properly caparisoned, and adorned with the figures and *tinctures* of his arms. He was to be preceded by his esquire, bearing in his right hand his master's spear, with the pennon of his arms; and in his left, his helmet adorned with lambrekins, or the *favours* of his mistress, also of his proper tincture. When he approached the place where the tournament was to be held, he was to signify his arrival by the sound of a horn or trumpet; on this the judges of the field met him at the barrier, to whom he gave in his name, his helmet, his arms, and the proofs of his descent; these were all regularly and carefully registered; and for some days previous to the tournament, his shield was hung up on a tree in some conspicuous place.*

The practice of thus exposing the shields of those who meant to engage in the tournaments had two objects; in the first place, it was considered as a challenge to all that were willing to *just*; the page or esquire, was appointed to watch them, and whoever touched the shield of another knight, was immediately marked down in the register books, as his combatant. If the shield was touched with a blunt weapon, the combat was to be of that description; if with a sharp weapon, the combat was to be with weapons of that kind. In the second place, the public exhibition of the shields gave those who meant to attend the tournaments, and especially the ladies, an opportunity of knowing their respective owners; and if a lady discovered the shield of a knight, against whom she had any just reason of complaint, by simply touching it, she appealed to the protection and justice of the judge of the field against the culprit. If he, on enquiry, found that the complaint was well-founded, the knight was instantly punished, and forbidden to appear at the tournament; and if he did, a shower of blows with switches, laid on by the other chevaliers, and even by the ladies themselves, drove him ignominiously from the lists.

The eve of the tournaments was celebrated by justs on a smaller scale; these were called essays at arms. In these it was lawful for the esquires to engage, with arms light and easily managed, sometimes with those knights who had been recently created. If in these inferior and preparatory feats of arms, any esquire particularly distinguished himself, he was made a knight, and consequently was authorised to engage in the grand tournament.

The laws respecting the dress and arms that were to be worn at tournaments, and the mode in which the combats were to be conducted, were strictly laid down. The lance, the sword, the mace, and the dagger, were the arms allowed. The dress of the knight consisted of a long and flowing robe, which reached down to his heels. It was unlawful to strike with the point of the sword; to wound the horse; to aim a blow at any part but the face and the body; and to attack a knight when he had taken off his helmet. The judges of the field, whose business and duty it was to enforce these laws, as well as to assist the ladies in awarding the prize, were selected from the ancient knights (*veterani*), who, no longer able to engage in war or tournament, applied their wisdom and skill to regulate them.

The place destined for the tournament was fitted up with the utmost magnificence. The benches that surrounded it were filled with princes, nobles, and ladies; while the judges of the field and the heralds took their station, where they could best discharge their respective duties. When a chevalier entered the lists, who had never before engaged in a tournament, the herald, in proclaiming his approach, called upon him to remember whose son he was, and not to disgrace his ancestors. It was customary for each cavalier to enter the lists, conducted, and sometimes led by a silken chain, by their mistresses, whose favour they wore, and whose name they proclaimed as a title of honour and a presage of victory.† The first action of the knight was to wave his pennon, inscribed with religious symbols, in the air, in the form of a cross; thus displaying by the first words he uttered, and the first action he performed, his devotion and his gallantry.

As the champion of each dame was successful or otherwise, he was cheered by her applause, or roused by her approaches. If, during the combat, he lost the favour which she had given him, she presented him with another; and it not unfrequently happened, that the zeal of the lady was so outrageous and indelicate, that she deprived herself of more than the ornamental parts of her dress for this purpose. But to suffer the *favour* of his lady to be taken from him by his adversary, and not either to preserve it, or if he did lose it, to lose it by its being cut to pieces, was regarded as highly disgraceful, and as the certain cause of his mistress's estrangement.

---

* Sometimes the shields were hung up in a neighbouring monastery, to which, or to the church, the arms of the horse, with which the fortunate champion had gained his triumph, were not unfrequently offered as a gift of religious gratitude.

† In the time of Edward III. ladies of the first distinction attended the tournaments on horseback, armed with daggers, and in a kind of military dress.

The ladies also bore another conspicuous and important part in the tournament. They had the right to appoint a judge of the peace, the touch of whose lance, the sign of the pleasure of the ladies, rescued those who, through inadvertence, had violated the laws of the tournament, from the attacks of his companions.

But it was at the close of the day, when the sports were finished, that the high privilege, and the most pleasing duty, of the ladies was exercised. By them the prize awarded by the judges was to be bestowed on the fortunate chevalier.* It was their duty to take off his armour; and when he received from their hands the prize, he was permitted to take, and the most noble and scrupulous were not ashamed to receive, a kiss. He was afterwards dressed in the richest robes, placed at table in the seat of honour, and treated with every mark of respect and dignity. His exploits were entered by the heralds in a register; and the minstrels celebrated his victory.

After the principal tournament was finished, it was customary to engage in another, which was denominated "the lance for the ladies." In this, if possible, the knights exceeded their former efforts in skill, enterprise, and valour.†

Single combats.

Single combats were fought, either when one knight brought an accusation against another, of having broken the laws of God, of the land, or of chivalry; or between knights of different nations in time of war; or to revenge private quarrels; or to prove the superior beauty and qualifications of a mistress.

Judicial combats.

In judicial combats, the accused person was obliged to appear before the judge of the field on an appointed day; and if he denied the accusation, the challenge was thrown down, and accepted by each party. The judge first took up the challenge of the defendant, and afterwards that of the accuser. They were both immediately after that confined till the day of combat, or committed to the care of their respective friends, who became bound for their appearance, dead or alive, till the appointed day. If then either party did not make his appearance, his surety was ignominiously, and sometimes capitally punished. If he had died in the mean time, the surety brought the dead body into the lists; if it happen to be the accuser, the defendant has no other mode of proving his innocence, but by throwing the body out of the lists. Lindsay mentions a curious case, where the dead body was so heavy, that the other party could not lift and throw it without the barriers. The surety of the dead person therefore contended, that as he had neither *confessed,* nor been cast out of the lists, and the *peremptory* day was past, his friend had won his action.‡

On the day of combat, the parties took a solemn oath, that they had no weapons, but such as were allowed, and had been assigned them by the marshall; that they carried about them no spell and enchantment; and that they trusted in nothing but God, their own prowess, and the justice of their cause. Their hair was cut short round the forehead and about the ears; and their bodies had been generally previously anointed with oil. Before the combat began, each party repeated his challenge, and his defence or denial. Immediately afterwards they entered the lists, which were protected and surrounded by four or more knights. An hour was then spent in devotion; and when this was finished, the cry of the marshall, "Come forth," was the signal for the rencontre. If, on the appearance of the stars, the combat was not finished, the accused was deemed victorious, and consequently his innocence was established; but it was established less equivocally, and more honourably, by the death of his antagonist. The conqueror was not obliged to show mercy, unless the vanquished begged it;—the dagger was used to dispatch the fallen foe. When either of the combatants was dying, a priest attended to confess him; and it was deemed honourable, and a proof of high courage, to be confessed and die without taking off the helmet. The accused, if vanquished, sometimes was not put to death on the spot; but led forth, hanged, and beheaded;—even this was done, in cases of murder and treason, to the dead body of the culprit, who had been slain in combat. It sometimes happened, that one person engaged several;—in this case, after he had defeated one of his antagonists, he was led out of the lists by the judges, who disarmed him, and gave him three sops, probably of bread steeped in wine, before he renewed the combat.

Simple affairs of arms.

In simple affairs of arms or of gallantry, the challenge was given by touching the shield, as in the case of tournaments. There was generally a shield of peace and another of war hung up; and the combat was "to outrance," or otherwise, as one or other of these was touched. Sometimes the shield, adorned with an *emprise*, a ribbon or chain, was hung up: if the emprise was snatched away, the combat was for outrance; if only touched, for simple feats of arms. During sieges, single combat was often held on the drawbridge or barriers of the town, between knights of the opposing parties. "The former, as the more desperate place of battle, was frequently chosen by knights, to break a lance for honour and their ladies love," (Scott's *Minstrelsy*, iii. 36.); and as this mode was very dangerous, the mode of attack and defence was early and regularly taught all knights. In simple affairs of arms or gallantry, the vanquished was generally disarmed, and led forth out of the lists ignominiously. In affairs of gallantry, the vanquished was obliged to confess the superior charms of his antagonist's mistress. In combats, as well as in tournaments, if either party was carried by his horse without the lists, he was reckoned to have lost the guerdon of his valour.

---

* The decision turned upon several circumstances: he who had broke the greatest number of lances; or who had exhibited the greatest skill in attack and defence with the lance and the sword; or who had continued on horseback the longest; or who, in the thickest combat, had been able to keep his helmet on the longest, without being obliged to take it off, for the purpose of breathing; was, according to circumstances, or the opinion of the judges, declared victor. The prize was sometimes very valuable; sometimes only a wreath placed on his head by the ladies, and called in the language of romance, "The chaplet of honour."

† The combat of the lance on horseback was deemed the most honourable; that with the sword the most dangerous; the superior honour of the combat with the lance was marked by the following circumstance: When a knight came to a tournament for the first time, he had to give a certain sum to the herald; if his first combat was with the lance, what he paid freed his future combat with the sword; but what he paid, if his first combat was with the latter, did not free his future combats with the lance; hence, the maxim in chivalry, the lance frees the sword, but not the sword the lance.

‡ Lindsay's MS. *Heraldry*, quoted by Dr Leyden, *Complaynt of Scotland,* Introduction, 86.

Vows of the knights.

Beside the solemn oath of chivalry, which a knight took when he was admitted into the order, and which he renewed very frequently, he was accustomed to make vows of enterprise. The occasions on which these were taken were numerous. As a young knight was said not to have won his spurs till he proved his valour and his gallantry, he was obliged to wear on his arm some mark of his inexperience and thraldom, which he solemnly vowed not to remove till he had achieved some feat of chivalry. At solemn feasts and tournaments also, in order to recommend themselves to the ladies, the knights used to take vows of enterprise; and, as a mark of their engagement, chains of gold were fastened to their arms by their favourite mistresses, who at the same time granted them a reluctant kiss.

The most solemn vow that a knight could take, was by the peacock and the ladies. The latter needs no explanation; the former took its origin from the circumstance of the peacock forming the most splendid and magnificent part in grand entertainments, given by princes, on occasions of chivalry. After being roasted, it was again dressed in its plumage,—a sponge, dipt in lighted spirits of wine, was placed in its bill; and it was thus brought into the hall on a gold or silver dish, by the most distinguished and noble ladies. In this state it was presented to each knight, who vowed by it, and the ladies who were present. The bird was then placed on the table, cut up with great solemnity and parade, and distributed among the guests.

These vows were frequently of the most extravagant nature:—"To be first in advancing, and last in retreating; to strike upon the gate of a certain fortress of the enemy; to fight blindfold, or with one arm tied up; to carry off a banner, or to defend one;" were among the more usual and rational subjects of their vows. Froissart relates, that when Edward III. began his war against France, many of the knights of England bound up one of their eyes with a silk ribbond, and swore before the peacock and the ladies, that they would not make use of the other eye, till they had accomplished certain deeds of arms: and Bertrand du Guesclin swore, at the siege of Montcontour, that he would neither eat meat, nor undress himself, till he had taken it. The besieged, on the other hand, often swore, that they would devour one another, rather than yield up the place. John of Bourbon, in 1414, in order to acquire the favour of his mistress, vowed; that he and sixteen other knights and esquires would wear, every Sunday, for the space of two years, a chain on their left leg, of gold for the knights, and of silver for the esquires, till they had met with and engaged an equal number of their respective ranks.

As soon as a knight had made his vow, and fastened on his *emprise*, he prepared himself for the accomplishment, by prayer and fasting. He entered the church, where he confessed himself, and in which, as has been already noticed, he offered up his arms, if he proved successful. When the *emprise*, the mark of his engagement, was once fixed, either on his armour or his person, he could not free himself from it, till he had fulfilled the conditions of his vow; or till he had met another knight, on whom, after having defeated him in single combat, he fastened it.

Amusements of the knights.

The knight filled up his leisure hours with different kinds of amusements. Hawking, or the mystery of the rivers, so called, because wild fowl were principally taken; and hunting, or the mystery of the woods, were his favourite sports. Of course, his dogs and his falcons were the objects of his particular care and attention. When he rode out, his esquires carried his hawks, while the falcon, his special favourite, was perched on his own finger. No higher praise could be given to a knight, than that he was equally celebrated for, and equally able to converse on, subjects relating to hawking, hunting, arms, and love.

In his castle he amused himself with hearing read the exploits and adventures of the most renowned knights; or the songs of the minstrels; or the sports or tricks of the jonglers; or with games at chess, dice, and backgammon. The former, he was carefully taught from his infancy; its resemblance to war, that grand object of his life, made it his favourite game. He generally played at it with the ladies; but it was not permitted to play for money; or, at least, the sum he might lose in one day was strictly limited. Dice were regarded as not so honourable a game. An amusement is also mentioned in ancient writers on chivalry, the nature of which is not clearly described; it seems to have consisted in setting up a wooden castle, so loosely made, that the parts of it would easily fall to pieces, and in throwing at it with wands. A game at bowls, played in alleys, seems likewise to have filled up the leisure hours of the knights.

Although the castles, and entertainments of the knights, have been incidentally touched upon, a few particulars may be added. Towards the court yard of the castle, there were generally open galleries, from which the ladies might view the procession, and the sports, and distribute the prizes at tournaments. St Palaye supposes, that the barriers, which enclosed the houses that were occupied by the princes of the blood and the grand officers of the crown, in Paris, before the revolution, took their origin from the circumstance, that they alone could celebrate justs and tournaments, and were, in fact, the lists erected and used for that purpose. In the great hall of the castle, there were two longitudinal seats, in the middle of which, and generally fronting the southern door, was a bench more raised than the rest. This was the seat of honour. At solemn feasts, moveable tapestry was placed behind it, and a canopy hung over it. When it was intended to receive a knight, who had distinguished himself in battle, or in feats of arms, with more than usual dignity, he was placed on the high table, to which he was permitted to ride through the hall on his war horse, adorned with his armorial bearings, and all its trappings. In the language of chivalry, he was, when thus placed, said to begin the board.

At their entertainments, but especially in the evening, different spiceries, sweet-meats, and wines, were served up by the esquires; *clairet*, or wine clarified with spices; *pimeate*, which consisted of wine, spices, and honey; and burnt wine, were most commonly used. Just before they retired to bed, *vin du coucher*, consisting of wine and the other materials just mentioned, was given to each guest. At the close of the entertainment, either the esquires brought in water for the guests to wash themselves, or the guests went, for that purpose, to another apartment; in the latter case, the lady of the castle led out first the guest which she wished particularly to distinguish.

Ceremony of degrading knights.

As the dignity, the duty, and the privileges of chivalry were so great and numerous, and as the ceremonies, by which an esquire was admitted into the order, were solemn and imposing, so also was the ceremony by which an unworthy member was declared to the world stripped of his dignity and his privileges, and deficient in his duty. This degradation took place, when a knight was guilty of treason, murder, or cowardice; sometimes, even the circumstance of his being defeated in single combat, as in the case of Henry de Essex, in 1163, who was vanquished in a duel with Robert de Montfort, was sufficient to degrade him.

The knight who was adjudged to this punishment, was led upon a scaffold, his spurs were hewn off by a servant, his sword broken over his head, his armorial bearings torn to pieces, and his shield tied, with the upper part downwards, to the tail of a horse, was dragged along the ground. This position of the shield was deemed a symbol of the death of a chevalier, and a chevalier who had dishonoured himself was looked upon as dead. To follow up this idea, the priests, after having recited the funeral ceremony, repeated, over his head, the 107th Psalm, which contains imprecations on all traitors. Thrice the herald at arms demanded the name of the criminal; and as often as the pursuivant at arms named him, the former replied, that this could not be the name of the knight they said, since in him he beheld only a traitor, at the same time pronouncing him no longer a knight but a knave. On this the herald threw over him a bason full of warm water, to efface the sacred character of chivalry, which the *accolade* had bestowed. He was afterwards taken from the scaffold, with a cord fastened under his arms, laid on a hurdle, covered over with a pall, and placed thus in a church, where the funeral service was again said over him.

For lesser faults, a knight was degraded by being obliged to ride on a work-horse; or by being deprived of part of his armorial bearings. There was also a kind of punishment inflicted on him, when he misbehaved, ridiculous, and tantalizing, rather than severe. This consisted in snatching away the cloth from the table where he was eating, if he presumed to seat himself near unsullied knights; and if thus disturbed, he went to the table of the esquires, he was there treated in the same manner. Sometimes, when a knight had been ignominiously conquered in battle or in feats of arms, he voluntarily condemned himself to abstain from chivalry for a year and a day.

Employment of the aged knights.

As a chevalier advanced in years, he gradually withdrew himself from the employments of knighthood. He first abstained from engaging in tournaments; and when he had reached his sixtieth year, he was authorised to decline any challenge, and exempted from his fief; he was, however, expected to give his horse and his arms to the lord under whose banner he had fought, and under whom he had held his lands. These were in exchange for his personal service; if he held no fief, he generally, at the close of his military life, laid his arms at the feet of his mistress, or deposited them in a church. It not unfrequently happened, that the religious feeling, which had been early instilled into his mind, and which, in the prime of his life, had been overshadowed by his love of arms and his gallantry, broke out with redoubled force in his old age; in this case, he exchanged the duties of a chevalier for those of a monk, or taking up the cross, went on a pilgrimage to the Holy Land. A Provençal poet, in his Lay of a Bachelor at Arms, expressly states, that, in order to obtain and deserve the appellation of a perfect chevalier (*Preudhomme*), it is necessary that the last years of a knight should be spent in this manner.

Ceremonies at the funerals of the knights.

If a chevalier was killed in the field of battle, his funeral rites were celebrated with more regard to his glory than to pomp and magnificence. If he was killed storming a castle or a fortress, his body was buried in the breach. When he died a natural death, the ceremonies of his funeral were varied according to circumstances; if he had performed, or even only planned and begun a crusade, he was carried to the grave armed, with his legs crossed; and the sculpture on the tomb was in the same attitude.* The swords of the most renowned and valiant knights, which had been the instruments of their victories, were held in the highest estimation; they were sought after with avidity; and when obtained, they were hung up in the arsenal or great hall of the castle, as honourable monuments, and as proper incitements to rival the courage of those, by whom they had been so often wielded with success, in advancing the glory, and performing the duties of chivalry.

Knight errantry.

A discussion on chivalry, which should omit the subject of knight errantry, would be deemed incomplete in the most curious, if not the most interesting point; and yet it is extremely difficult to obtain authentic evidence respecting the knight errants. In the old romances, they occupy the most distinguished place; but in the old historians and chronicles, only a few faint traces of them are to be found.

The spirit and the practice of going in quest of adventures, arose partly from the very nature of the institution of chivalry, and partly from the custom of knights travelling wherever tournaments were to be celebrated: this spirit and practice were undoubtedly increased by the Crusades. In their expeditions to the Holy Land, knights would necessarily meet with many opportunities of displaying their valour and their gallantry, and of performing that part of their vow, which bound them to succour the widow, the orphan, and the helpless. So desirous were the young knights of seeking and obtaining opportunities of signalizing themselves, and of acting in the capacity of the avengers of the injured, and the defenders of the weak, that they frequently bound themselves to spend the first years of their knighthood in visiting foreign lands, in order to make themselves "perfect knights." For this purpose, they studied the customs of different countries, and made themselves acquainted with the rites of their tournaments, and the ceremonials of their courts. The character of their sovereigns, and especially of their most celebrated ladies, was also a part of their preparatory knowledge. Thus fitted for the object they had in view, they set out, attended by their squires; and they chose that road, which they thought would present them with most opportunities of meeting and overcoming danger, in the punishment of crimes, in the repressing of violence, in the protection of insulted, or in the liberation of confined damsels.

A real knight-errant, more frequently met with in romances than in history, clothed in green,—for that was his favourite colour, as expressive of the freshness of his age, and the vigour of his courage, †—and with nothing but what was absolutely necessary for attack or defence, chose his path through forests or unfrequented tracks; for his food, he depended entirely on the animals he killed; these he cooked in the most simple and rude manner; a stone served him for a table, and it also served him to press the blood from the newly killed animal. Thus prepared, he made his scanty and savage meal, with some salt and spices, the only things he carried with him, beside his arms. For a year and a day he wandered in this manner, in quest of adventures; sometimes reaching and punishing those crimes which were beyond the knowledge, or the reach of the law; and not unfrequently committing injustice and violence in the very act of relieving the oppressed, or punishing the criminal.

---

* Olivier de la Marche, however, as quoted by St Palaye, says, that unless a knight was slain in battle, his banner, his standard, and his pennon, were not carried with him to the grave; but only one or two of these.

† When a knight errant had reason to despair [illegible] of his [illegible], the colour of faded leaves.

Perhaps the most striking instance of knight-errantry that is well authenticated, is given by Brantome. This author relates, that Galeas of Mantua, in gratitude to Queen Joan of Naples, for having danced with him, made a vow that he would become a knight-errant till he had conquered and brought into her presence two knights. At the end of a year, which he spent in combats, in England, Spain, Germany, Hungary, and other parts, he accomplished his vow.

The fraternities or brotherhoods, which sprung out of chivalry, or at least were rendered more frequent and better organised by it, rest on surer authority. It has been already observed, that a similar institution existed among the Scandinavians; and it is remarkable, that one of the most common modes of entering into the fraternities of chivalry, was by mingling the blood of the parties,—a practice usual among the Scythians. Sometimes religious ceremonies were employed, and not unfrequently an exchange of arms was the proof and bond of fraternity. So predominant and indispensable was the mutual obligation thus formed, that a knight was justified in not attending to the call of a suffering and oppressed female, if, at the same time, his brother in arms required his presence. His sovereign, however, had a superior claim upon him; and the obligation was dissolved, when war was declared between the countries to which they respectively belonged.

The union was deemed so intimate, that all the members of the fraternity wore the same dress, and carried the same arms; and no member could admit, or acknowledge as his friend, any who was not also the friend of the fraternity; as they were mutually bound to assist one another, they could not undertake any enterprise except in concert. The principal object of the fraternities was to free their country from robbers; to go on expeditions against the Infidels; and to accomplish with more effect and glory all the purposes and duties of chivalry.

These fraternities were entered into, sometimes for life; but more frequently only during a campaign, a battle, a siege, or a war; at the termination of the engagement, each party rendered up an exact and faithful account of what he had gained in booty or in presents, or of what he had expended or lost.

Education, &c. of the ladies in the time of chivalry.

The education, the manners, and the employments of the ladies, in the days of chivalry, have, in the course of this article, been noticed with nearly as much fullness and minuteness, as the subject requires or admits of. The scattered observations on these points may be here briefly brought together, and a few additional circumstances introduced. The manners of the ladies were necessarily polite and courteous; for such they taught, and expected those of the chevaliers to be. Their principal ambition was to deserve and obtain the love of a valiant knight; but their idea of love led them to prefer his death to his dishonour. "According to the laws of gallantry, I should have loved him better dead than alive!" was the exclamation of a damsel, on hearing that her knight had escaped alive, but with the loss of his honour, while the knights of her companions had died the death of chivalry. To rouse him to enterprise, to reward him with her approbation, with her smiles, perhaps with a kiss, if victorious;—to shame him by her reproaches, if vanquished, were the great objects of her life. It was the business of the ladies to adorn the armour of the knights with *favours;* to take it off when the tournaments were finished; to bestow on them the prize; and to attend to them when wounded. They likewise joined them in playing at chess, backgammon, and dice. It is probable, that they sometimes took the diversion of hawking; at least, they scarcely ever appeared in public without a falcon on their finger, as a mark of their dignity. The bath was much used by them, not only for the purpose of preserving or increasing their beauty, but also for the sake of enjoying free and uninterrupted conversation. Their magnificence and luxury, like those of the knights, were great, and was discovered in their dress, and in all their domestic arrangements. One instance may be given: they had always burning in their chambers, while they were in bed, the most delicate and costly perfumes.

Effects of chivalry.

The effects which chivalry produced on the age in which it existed, the circumstances which led to its decline and extinction, and the traces of its character and influence that still appear, may be briefly and rapidly told.

The qualifications and duties that chivalry imposed and required, which have been so fully detailed and explained, though they were sometimes evaded or transgressed, sometimes altogether wanting in its knights, and too often overpowered by the ignorance and violence of the age, or mixed up with its vices, yet undoubtedly tended, in a very considerable degree, to give efficacy to laws in the time of their weakness, and to supply their place in many important cases, which they could not touch. This institution also infused humanity into war, at a time when the disposition of the age made it the almost constant business of life, and the ruling passion of all conditions of men; it introduced courtesy of manners, when men, from ignorance, and want of mutual assistance and intercourse, were naturally rude and uncultivated; it exacted and produced a scrupulous adherence to truth, at a time when the temptations to falsehood and breach of engagements were numerous, and the personal and social evils resulting from these vices, were imperfectly understood and feebly felt. It added an additional impulse and motive to that respectful and delicate attention to the female sex, (which distinguished the Gothic ancestors of Europe,) at a period when this attention, and the protection and support which accompanied it, were particularly necessary to them.

Decline and extinction of chivalry.

In sketching out the causes of the decline and extinction of chivalry, the period when they took place will be sufficiently marked. As it rose to splendour, and was embodied into form and regularity by the feudal system, so it fell along with it. The causes which broke up this system; the change of manners, habits, and pursuits among mankind in general, and of the principles and conduct of governments, and especially of their military and financial institutions, and of their mode of carrying on war, were fatal alike to the feudal system and to chivalry. The same era which witnessed the discovery of gunpowder and artillery, and the invention of printing, and in which there sprung up the seeds of commerce, witnessed and produced the decline of chivalry. All these circumstances operated on the habits and the manners of the age, and, in conjunction with the destruction of the feudal system, put a period to the existence of chivalry. As it arose principally from a peculiar state of society, the evils of which it was calculated to remove or alleviate, so it fell, when that state and those evils had given way to the general diffusion of knowledge and of wealth.

But the spirit of the institution may still be traced. "The humanity which accompanies all the operations of war, the refinements of gallantry, and the point of honour, the three chief circumstances which distinguish modern from ancient manners," at once demonstrate its extensive and permanent influence, and the beneficial nature and effects of its principles.

Reference to authors.

The authors that treat on the subject of chivalry may be divided into two classes:—1st, Those who have endeavoured to trace its origin and causes. Of these, some indulge principally in antiquarian research, and others in general reasoning; of the latter, the most celebrated are Hurd, in his Letters on Chivalry and Romance, which are appended to his *Moral and Political Dialogues*, in 3 vols 12mo; Gilbert Stuart, in his *View of Society in Europe*; Robertson, in his View of the State of Europe, prefixed to his *History of Charles V.*; and Herder, in his *Outlines of the Philosophy of the History of Man*. This author also in some degree unites antiquarian research with general reasoning. *Gibbon*, in his 58th chap. and 11th volume, has given a rapid, but masterly view of the origin and the principal features of chivalry. The antiquarian researches on this subject are to be found rather detached and scattered in different works, than in complete and regular treatises. The notes of Warburton and Tyrwhitt towards the conclusion of *Love's Labour Lost*; Warton, in his first dissertation prefixed to his *History of English Poetry*, and occasionally and incidentally in the *History* itself; Mallet in his Introduction to the *History of Denmark* translated by Percy; Percy, in his 3d volume of the *Reliques of Ancient Poetry*; Pinkerton, in his *Dissertation on the Scythians and Goths*; Dr Leyden, in the Introduction to the *Complaynt of Scotland*; and an anonymous writer in the *Monthly Magazine* for February 1800; have been already referred to, and supply curious and valuable information on the antiquarian branch of the subject. Notices on the same branch are scattered in Selden's *Titles of Honour*; in *Essais sur la Noblesse de France*, by Boullainvilliers; in *Histoire de l'Ancien Gouvernment de France*, by the same author; in *Les Recherches de la France*, by Pasquin; and in Ashmole on the *Order of the Garter*.

2d, The last named authors may also be consulted respecting the institutions of chivalry. But the most copious, authentic, and interesting author on this branch of the subject, is Mons. de St. Palaye, in his *Memoires sur l'Ancienne Chevalerie*,* either in his work, or in the author whom he cites or refers to, almost every particular respecting the institutions of chivalry, especially French chivalry, may be found. This work has been translated into German by Klueber, who has added many particulars respecting German chivalry. Some additional information on the laws and manners of chivalry may be gleaned from Lyttelton's *History of Henry II.* vol. iii.; Henry's *History of Great Britain*, vol. vi. (8vo edition); and especially from the ancient Ballads and Romances that have been edited by Percy, Ritson, Pinkerton, Ellis, and Scott, and in the notes by which they are respectively illustrated. It is hardly necessary to add, that Chaucer and Spenser, particularly the former, throw considerable light on chivalry; and that the notes of Tyrwhit to this poet, and the observations of Warton and Tod on Spenser, may be read with advantage.

CHLOANTHES, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY, p. 257; and Brown's *Prodromus Plant. Nov. Holl*, &c. p. 514. (*w*)

CHLORA, a genus of plants of the class Octandria, and order Monogynia. See BOTANY, p. 201.

CHLORANTHUS, a genus of plants of the class Tetrandria, and order Monogynia. See BOTANY, p. 126.

CHLORIS, a genus of plants of the class Polygamia, and order Monœcia. See BOTANY, p. 342.

CHLOROMYRON, a genus of plants of the class Polyandria, and order Monogynia. See BOTANY, p. 241.

CHLOROPHYTUM, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY, p. 195, and Brown's *Prodromus*, &c. p. 276.

CHOCOLATE. The *Theobroma Cacao* is a native of South America, and produces a nut, the kernel of which is the basis of chocolate, which has from time immemorial been an important article of food among the Indians, and which has become, since the discovery of America, an indispensable article of luxury to European Spaniards. The tree belongs to the genus *Theobroma*, of which there are three species, the *Theobroma Cacao*, already mentioned, the *Theobroma Gujanensis*, and the *Theobroma bicolor*. This genus belongs to the class Polyadelphia, and to the order Pentagynia. For the essential character, see the article BOTANY, p. 287. This tree is not now confined to the Spanish colonies; but is cultivated considerably in some of the British settlements. Prepared chocolate is very highly prized, although, from political considerations, it is altogether excluded from the British market by the legislature. The cacao-nut, however, is less exorbitantly taxed, and may be introduced; and that from the Caraccas is most valuable. The quality of the Spanish cacao varies, as well as that of the colonies of other nations in the western hemisphere. That of Orituco is superior to all the other kinds. Such is its compactness and density, that an equal bulk will weigh twenty per cent. more than that of any other cacao. The next in point of quality is the cacao of the coast, and last of all that of the interior.

Cultivation.

The cacao plantations of the Caraccas, are chiefly confined to the northern portion of that chain of mountains which skirts the coast of the province.

Much nicety and judgment are necessary in selecting a soil and situation appropriate to this kind of produce. The Spaniards, in judging of the fertility of the ground, do not trust to the results of analysis, to the colour, or to any character, except those derived from the luxuriance of the trees growing on it. The exposure should not be to the north; and the situation should be on the banks of a river, from which the benefits of irrigation may be derived in dry seasons, and against any sudden overflow, of which there are sufficient safeguards.

A piece of land having been chosen, it is cleared of all the natural vegetation. This is effected in several ways;

---

* This work has been translated into English by Mrs Dobson.

but the most common is to cut down the wood, allow it to dry very thoroughly, and then to burn it. The plantation is then drained; and small trenches are cut, so as to carry off all superabundant moisture. The cacao plants are then arranged either in straight lines, so as to make a cross, formed by the junction of the apices of two triangles, or in that of a square. The distance of the trees from each other should be fifteen or sixteen French feet in good soil, and about twelve or thirteen in that which is inferior.

It is peculiarly necessary to defend this tree from the scorching rays of the sun, and at the same time sufficient warmth should be afforded to secure the vegetation. This is done by planting it with the plantain tree and the erytrina, which answer all the objects desired. The whole plantation is guarded by the cassaoa plants. The cacao plants which are transplanted, should not exceed three feet in height; when they are larger they are less manageable, and more apt to die. The nurseries of the cacao require very fine land, well dressed, and free from wet. They should be sheltered from the sun. Small heaps of earth are collected, into each of which two seeds of the cacao are set. For the first twenty-four hours the rows are covered with plantain leaves. The ground is watered, if necessary, but no water is allowed to remain on it. The period best suited to this operation, is in the month of November.

The season, however, for planting the cacao nut, depends upon the situation of the plantation; where there is no abundance of water, the dry season; when there is a scarcity, the rainy season. The former is the best, when attainable, as the quantity of moisture can be easily regulated. During the period of transplantation, the plants must be kept perfectly dry. When the two seeds in each heap have germinated, the weakest plant is destroyed to give greater vigour to the remaining one. The plantain trees should be carefully cut down when they become old, lest in their fall they should injure the cacao trees.

Great care is bestowed in cutting off the superfluous branches of the young trees, so as to give them the benefit of the whole of the circulating fluids. All young shoots from the root are destroyed.

After the cacao walk is completed, great attention is necessary to keep it in order. The trees must be freed from the cryptogamous plants that grow on them, the earth worms must be destroyed, the walks must be cleared from all weeds, the trenches for drainage must be constantly deepened, so that after the roots have sunk five or six feet into the soil, the moisture may be equally diffused, for when there is too much the root decays. This precaution not only ensures the health of the trees, but also a larger crop. The branches should not be too often lopped, as when this is done the tree frequently dies.

The nut withers upon the tree from several causes, which frequently cannot be obviated. But we cannot enter so minutely into this subject as we wish, from the nature of our work.

There are two principal crops of cacao in the year, the first about St John's day, and the second about the end of December. Frequently the crop fails; and generally a considerable quantity of the nut is found to be decayed. Great benefit is said to be derived from gathering the fruit when the moon is waning, yet some intelligent people ridicule this opinion, as a mere prejudice, and impracticable to any extent, without a certain loss by the decay of a large portion of the fruit.

The people employed in gathering, carrying, and separating the external coat of the cacao nut, are selected with care; the gatherers are composed of those whose sight is good, so that no unripe fruit shall be pulled; the strongest and most active are the carriers; and the old infirm slaves open the shell and take off the husk. These two last operations are performed by two classes of the feeble old people.

Good cacao should be separated from that which is either indifferent or bad. In general there are four kinds of cacao in each crop: the ripe, the green, the perfectly formed, that which is worm eaten, and the rotten. Whenever the first of these (the ripe) begins to ferment, it should be separated. The unripe nuts should be covered with the leaves of the plantain for three days, in order that they may ripen thoroughly. All the nuts are then stored; and it is indispensably necessary, that no leaves or pieces of the shell, or any other refuse, should be left in the store-house. And this is to be attended whenever the store-house is cleaned out.

But previous to this storing of the cacao, it must be very completely dried in the sun, as moisture is highly prejudicial to its being kept good. The best criteria of its being dry, are its not crackling when broken, and not heating when collected into heaps. When imperfectly dried, the nuts become mouldy; and on the other hand too much drying renders it liable to decay.

When the crop is considerable, a hundred quintals of cacao may be put out to dry in the sun at once, unless the plantation has a sufficient number of hands to convey a larger quantity. Should the season be rainy, the cacao ought to be dried in large, well ventilated, and covered galleries, with which every plantation should be furnished. Mr Depons suggests that stoves might be advantageously introduced, although they are as yet unknown in the colonies.

The storehouses, in which the cacao is kept, ought to be floored and wainscoated, and a small chaffing dish, covered with a funnel, the pipe of which enters the heap of the produce, and diffuses the smoke throughout it. Some put bottles of vinegar, slightly covered, in the houses, as a preservative against worms.

The nuts which are slightly tainted, may be preserved from entire decay, by a slight sprinkling of brine, which might be used as a preservative. Thus both salt and smoke are found useful; yet, singular to say, they are only resorted to after the destruction has been partial.

One slave is equal to the management of a thousand cacoa trees, each of which yields one lb. in middling soil, and one and a half in the best. The mean in the Caraccas, according to Depons, is about 20 ounces per tree. So that the produce of 1000 trees will be 1250 lbs. of cacao, which, even at a moderate rate, is a very handsome return for the work of each labourer. The expences of cultivation and necessary machinery is very trifling; the various accidents to which this kind of produce is liable, are the only drawbacks that lessen the number of its cultivators.

The cacao tree is not in full vigour until the seventh or eighth year, (according to the situation of the plantation,) though, in some remarkable spots, it attains perfection in four years. It retains its vigour for 50 years.

The cacao tree is obnoxious to several diseases, the most common of which are induced by the injuries inflicted on it by several kinds of worms, of which we shall give Depons' account, and by parasitic plants. The first of these caterpillars is small, of an ash grey colour, which, on being squeezed, emits a noise like the hissing of cold water on red-hot iron. It has two small horns on its head. It is so tenacious of life, that its head retains some activity long after it has been separated from its body. It is deposited in small holes in the bark." The only mode of destroying it is by hand.

"At the beginning of the rainy season, another very destructive insect appears, and destroys the leaves of the tree. It is four inches long, of the thickness of one's finger, and of various colours. It is called *Goosino* by some, and *Angaripola* by others. These destructive creatures are sometimes so numerous, as to afford continued employment to the whole establishment in killing them. They are deposited by butterflies, which have escaped the vigilance of the planter. When they appear and fly about, fires, sufficiently large to attract their notice, should be made on different parts, and they always fly into the flames."

There is a third variety of caterpillars called *Rosquilla*, which infest certain districts. It thrives in the dry season.

There are also others called *Acerredores*, larger and blacker than the others, that destroy the bark. They gnaw the wood.

The caterpillars called *Vachaeos*, are also very mischievous in devouring the leaves and the flowers. The earth, in which they have their nests, must be taken away.

Parasitic plants that attach themselves to the cacao tree, must be removed by hand, or the tree will perish.

The cacao tree is subject to blotches on the bark, which must be extirpated by the knife.

Stags, monkeys, and other animals, destroy the tree and its produce. The precautions to guard against their incursions must be suggested by local circumstances.

Chocolate is a well known paste, the basis of which is the cacao, and occasionally other ingredients are added to heighten its flavour. The rudest mode of preparing the chocolate, is by roasting the nut in an earthen pot, then grinding it between two stones, and last of all by moulding it into any form by the hand. The more improved method is the following one: After the cacao has been properly roasted and freed from every impurity, it is pounded in a mortar into a coarse powder, which is sufficiently ground on a stone to the greatest degree of fineness, and heated, when it is put into cylindrical or flat moulds, in which it congeals and is fit for use. The Spaniards mix spices of different kinds, besides large quantities of drugs, which are offensive to some palates. In England and France, Vanilla sugar, and occasionally cinnamon, are the ingredients that are added. The chocolate manufactured in this country pays an inland tax of about 1s. 6d. per pound; and must be wrapped up in stamped papers. After a notice of three days, private families may make chocolate for their own use, provided, that not less than half a hundred weight of cacao nuts be used at once.

Although foreigners prefer the Spanish chocolate, that which is prepared in this country is better triturated, and does not yield the quantity of oil which renders the other so disagreeable. When well prepared and properly boiled, (which is an operation of more delicacy than is commonly imagined) it is an excellent, nutrient food for people whose stomachs are weak.

Chocolate has had many virtues ascribed to it, although modern physicians do not recognise them. Its chief virtue appears to consist in its being very agreeable to most palates, easily digested, and very nutritive.

Chocolate, fresh ground, and cooled in tin vessels, becomes highly electrical, as was observed by Mr Henley. This property it retains until it has been much handled. It also loses it on being dried and powdered, but regains it when the chocolate is well mixed with some olive oil in an iron pot. These facts have given rise to some conjectures, which we need not repeat. See *Voyage a la Terre-ferme par* Depons, &c.; Cullen's *Materia Medica*; *Willdenow*, &c. (C. M.)

CHORAL FUND. Among the numerous benevolent institutions which receive the patronage and support of the British public, is an institution called the Choral Fund, established in London, which had its origin in the active zeal of Messrs John Farey, Joseph Doane, Robert Willoughby, Leonard Willshire, Thomas Elliot, and other members of private societies, for practising choral music once a week. These gentlemen having, in 1791, projected a plan of uniting these societies, and establishing a common fund for the relief of choral vocal performers in sickness, and for their widows and orphans, the plan was no sooner submitted to the late Dr Samuel Arnold, than he patronised it in the most liberal manner, and assisted in conducting, a public concert annually, for the benefit of this fund, which met with the most flattering support from the public. On the death of Dr Arnold, Messrs Greatorex, Harrison, and Bartleman, handsomely came forward to lend their professional aid in conducting the concerts, by which, and the high noble patronage which the institution has progressively received, its credit and funds have been rapidly increasing, and it has already done extensive good. The Prince Regent, and the Royal Dukes of Clarence, Sussex, and Cambridge being at present patrons, and the Duke of Manchester president. Among a most respectable list of vice-presidents, the name of the lord mayor of London, for the time being, has always appeared for several years back, with many aldermen, some eminent musicians, &c. (ς)

CHORD, in Music, is sometimes used synonymously with *Consonance*, to denote the combined effect of two musical sounds heard together, but more commonly practical musicians and theorists intend *three* sounds, at least, to be heard together, to constitute a chord; and these they distinguish by various names, as accidental, borrowed, common, complete, connecting, direct, equivocal, essential, uncommon, &c. or, the added sixth, diminished seventh, extreme sharp sixth, fifth and sixth, fourth and sixth, redundant sixth, second and fourth, second and third, sixth, sixth and ninth, sixth and seventh, third and fourth, &c. It is almost general with writers on the theory of music, to use only the Arabic numerals to express chords. Thus the common chord they denote by $\begin{smallmatrix}8\\5\\3\end{smallmatrix}$ or $\begin{smallmatrix}3\\8\\5\end{smallmatrix}$ or $\begin{smallmatrix}5\\3\\8\end{smallmatrix}$, &c. and when sharps or flats occur annexed to these, in figuring thorough-bass, these last generally have reference to the sharps or flats affixed to the beginning of the piece or stave, usually called its signature; but they are not in the habit of distinguishing the major from the minor intervals, that enter into the composition of chords, by particular marks, though the same is often much wanted. The Rev. Henry Liston, in his *Essay on Perfect Intonation*, p. 50, has in some degree remedied this defect, by the use of the Arabic numerals, 2, 3, 4, 5, 6, 7, and 8, for the minor intervals of these names, and the Roman numerals, I, II, III, IV, V, VI, VII, and VIII, for the major intervals; by the use of ♭, affixed to these Arabic numerals, to denote the depression or lessening of a minor interval, either a medium or a minor semitone, S or S (see our Table of Intervals, Plate XXX. in Vol. II. ;) by adding ✱ to the Roman numerals, to denote the elevation or enlarging of a major interval, by S or S, according to their places in the scale; and by using also the *grave* and *acute* marks, ` and ′, affixed likewise to the numerals, to denote the depression or elevation of a major comma C. Thus the chord called the common chord is marked, $\begin{matrix}\mathrm{V}\\\mathrm{III}\end{matrix}$ or $\begin{matrix}\mathrm{VI}\\4\end{matrix}$ or $\begin{matrix}6\\3\end{matrix}$, the octave being here understood. The chord of diminished seventh by $\begin{matrix}\flat 7\\5\\3\end{matrix}$, and its inversions by $\begin{matrix}\mathrm{IV}\\5\\5'\\\text{✱}\mathrm{VI}\end{matrix}$, $\begin{matrix}\mathrm{VI}'\\\mathrm{IV}\\3\\\mathrm{VIII}\end{matrix}$, and $\begin{matrix}\mathrm{VI}\\\mathrm{IV}\\\text{✱}\mathrm{II}\\\mathrm{VIII}\end{matrix}$, (page 90.) The redundant sixth by $\begin{matrix}\mathrm{V}\\\mathrm{III}\end{matrix}$, $\begin{matrix}\mathrm{VI}\\\mathrm{III}\end{matrix}$, and $\begin{matrix}\mathrm{V}\\\mathrm{III}\end{matrix}$, (page 99, &c.)

It were still, however, desirable, that the ambiguous or variable signification of ✱ and ♭ were avoided, in marking chords sometimes to mean S and sometimes S, as Mr Farey has shewn in the *Philosophical Magazine*, vol. xxxix. p. 375; especially as this use of these characters interferes with their established use in figuring bases. The ambiguity of the term major and minor, sometimes denoting S and sometimes S, is not a parallel case, as Mr Liston seems to infer, in his note, page 137; because it is only by an original defect, or a partial view in the framers of the nomenclature of intervals, that a minor and major third, for instance, had not separate and independent names; and the same ought not now to be imitated in coining new terms, or inventing marks, when the precise values of intervals being understood, it is unphilosophical and improper to mark or call the departure from *fixed terms*, as II, III, IV, &c. by the mark ✱ or term redundant, having each different significations (S and S,) or from 2, 3, 4, &c. by the mark ♭ or term diminished, sometimes measured by S and sometimes by S in such cases. It seems that Mr Liston was deterred from using the terms flat and sharp, (according to his marks,) instead of diminished and redundant, by the absurd and ambiguous language of those writers who still often use flat and sharp synonymously with minor and major, and say a flat third, or a sharp sixth, when they mean the minor or major of these respectively. In Mr Liston's work, already quoted, the values of the several intervals, in all the several chords that occur in composition, are distinctly marked as above, and their peculiarities of effect on the ear, as exhibited on the extended or harmonic scale of his organ, are pointed out, and appear to offer much new and curious speculation and use to the scientific and practical musician. CHORDS, VIBRATION OF. See ACOUSTICS and VIBRATION.

CHORETRUM, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 172; and Brown's *Prodromus*, &c. p. 359.

CHORLEY, a town of England in Lancashire, situated near the source of a rivulet called Chor, which, taking its rise from several springs to the east of the town, falls into the Yarrow, a large river which waters the south-east part of the township. The town, which is tolerably well built, is not distinguished by any public edifices of great importance. The parochial chapel, dedicated to St Lawrence, is ornamented with numerous figures and hieroglyphics, and is supposed to be of Saxon structure. The prison stands at the south end of the town; and there are several dissenting meeting-houses, a poor-house, a grammar school, six alms-houses, and several Sunday schools. The cotton manufacture is carried on here to a great extent, and nearly a third of the whole population are employed in it, and in bleaching, printing cottons, fustians, calicoes, and muslins. Numerous mills are put in motion by the Chor and the Yarrow, while extensive bleaching grounds and printfields occupy their banks. The trade of the place derives great benefit from two canals, viz. the Liverpool and Leeds direction, and the Lancaster canal. The principal productions of the vicinity, are coal, lead, and alum, marl, slate, and freestone of various kinds for flags and millstones. The court of the bishop of Chester is held here twice a year by proxy. According to the population returns in 1811, the parish of Chorley contains,

Inhabited houses	902
Families that occupy them	912
Families employed in agriculture	100
Do. in trade and manufactures	790
Males	2426
Females	2756
Total population	5182

CHRIST-CHURCH, a borough and market town in Hampshire, is pleasantly situated at the conflux of the Avon and Stour. The principal building in the town is the church, which is large and interesting. Parts of the old castle are still standing, which appear to be portions of the keep and of the state apartments. The hotel, which has been recently built, and is fitted up with every accommodation, commands a delightful prospect of the sea, and of the Needle Rocks at the west end of the Isle of Wight. There is here also a poor-house, and several friendly societies. The inhabitants are principally employed in two breweries, and in the salmon fishery. The lower classes of females employ themselves in knitting stockings, and children find employment from a manufacture of watch spring chains, which has been established a few years ago. According to the population returns in 1811, the borough contains,

Inhabited houses	303
Families	327
Do. employed in agriculture	28
Do. employed in trade	145
Males	682
Females	871
Total population	1553

(*w*)

CHRISTIAN I. II. III. IV. V. See DENMARK.

CHRISTIANA, SANTO. See MARQUESAS ISLES.

CHRISTIANA, a city and sea-port town of Norway, in the government of Aggerhuus, is situated at the extremity of a bay of the same name, which runs almost sixty miles up the country. It is covered with a number of islands of various sizes, filled with mountains rocks, and rising from the water in the most beautiful and picturesque forms.

The town, which covers a considerable extent of ground, is divided into the city and suburbs of Waterlandt, Peterwigen, and Fierdingen, the fortress of Aggerhuus, and the town of Opsloe. The city was rebuilt after a plan designed by Christian IV. in which the streets were at right angles to each other, and all of them 40 feet wide.

The town has thus a great appearance of elegance, which is increased by the cleanness with which it is kept. The principal public buildings and establishments are, a gymnasium or Latin school, the parish church, a house of correction, a bank, and a printing house. The Latin school, endowed by Christian IV. in 1635, is governed by an upper and under master, and three assistants. In 1784, it contained only 37 scholars. A collection of 6000 volumes, lately left to the town by M. Deichman, has laid the foundation of a public library. Many attempts have been made by Mr Anker, to establish a university in Christiana, but this wise plan has hitherto been prohibited. Such is the low state of literature, that there is not even a bookseller's shop in the town, and when any book is wanted, it is ordered from Copenhagen or Hamburgh. The castle of Aggerhuus, which stands on a rocky eminence on the west side of the bay, at a short distance from the town, is strong though small. The garrison in the time of war is 1000, but during peace it is reduced to 500.

"Christiana," says Mr Coxe, "has an excellent harbour, and carries on a considerable trade. The principal exports are tar, soap, iron, copper, planks, and deals; alum manufactured at Mr Cooper's works for about £3000; iron from the four works of Borum, Edswold, Narkedahl, and Ondahlen, £14,000; copper from Foldahl, £10,000; planks and deals, £90,000, principally to England.

The planks and deals are of superior estimation to those sent from America, Russia, and from the different parts of the Baltic, because the trees grow on the rocks, and are therefore firmer, more compact, and less liable to rot than the others, which chiefly shoot from a sandy or loamy soil. The planks are either red or white fir, or pine. The red wood is produced from the Scotch fir, and the white wood, which is in such a high estimation, from the spruce fir. This wood is the most demanded, because no country produces it in such quantities as this part of Norway. Each tree yields three pieces of timber eleven or twelve feet in length, and is usually sawed into three planks. A tree generally requires 70 or 80 years growth, before it arrives at the greatest perfection.

The environs of Christiana not yielding sufficient planks for exportation, the greater part of the timber is hewn in the inland country, and floated down the rivers and cataracts. Saw mills are used for the purpose of cutting the planks, but must be privileged, and can only cut a certain quantity. The proprietors are bound to declare on oath, that they have not exceeded that quantity; and if they do, the privilege is taken away, and the saw mill destroyed. There are 136 privileged saw mills at Christiana, of which 100 belong to the family of Anker. The quantity of planks permitted to be cut amounts to 20,000,000 standard deals, twelve feet long, and one inch and a quarter thick."

The greater part of the country round Christiana belongs to the inhabitants of the town. An account of the family of the Ankers, distinguished by their opulence, their hospitality, and their intelligence, and of the splendid prospects in the neighbourhood of Christiana, will be found at considerable length in Kuttner's *Travels through Denmark, Sweden*, &c. Let. vii., and also in Coxe's *Travels in Poland, Russia*, &c. vol. v. 5th edit. p. 24. The population of Christiana in 1801 was 9005. East longitude 10° 28′ 45″, and north latitude 59° 55′ 20″. (π)

CHRISTIANITY.

This article is confined to the evidences of Christianity.

1. It is not proposed by us in this article, to enter either into the history of the Christian religion, or into its morality and doctrines. These we leave to the articles ECCLESIASTICAL HISTORY and THEOLOGY. We propose to confine ourselves to what have been called the *Evidences of Christianity*; or to exhibit a general view of those arguments, which go to prove that the New Testament is the authentic record of an actual communication from God to man.

There are two ways of verifying a human message.

2. Were a verbal communication to come to us from a person at a distance, there are two ways in which we might try to satisfy ourselves, that this was a true communication, and that there was no imposition in the affair. We might either sit in examination upon the substance of the message; and then from what we knew of the person from whom it professed to come, judge whether it was probable that such a message would be sent by him; or we may sit in examination upon the credibility of the messengers.

The first way is by attending to the internal evidence of the message itself, and is often insufficient.

3. It is evident, that in carrying on the first examination, we might be subject to very great uncertainty. The professed author of the communication in question may live at such a distance from us, that we may never have it in our power to verify his message by any personal conversation with him. We may be so far ignorant of his character and designs, as to be unqualified to judge of the kind of communication that should proceed from him. To estimate aright the probable authenticity of the message from what we know of its author, would require an acquaintance with his plans, and views, and circumstances, of which we may not be in possession. We may bring the greatest degree of sagacity to this investigation; but then the highest sagacity is of no avail, when there is an insufficiency of data. Our ingenuity may be unbounded; but then we may want the materials. The principle which we assume may be untrue in itself, and therefore might be fallacious in its application.

The second is by attending to the credibility of the messenger, and is more to be depended on.

4. Thus, we may derive very little light from our first argument. But there is still a second in reserve,—the credibility of the messengers. We may be no judges of the kind of communication which is natural, or likely to proceed from a person with whom we are but imperfectly acquainted; but we may be very competent judges of the degree of faith that is to be reposed in the bearers of that communication. We may know and appretiate the natural signs of veracity. There is a tone and a manner characteristic of honesty, which may be both intelligible and convincing. There may be a concurrence of several messengers. There may be their substantial agreement. There may be the total want of any thing like concert or collusion among them. There may be their determined and unanimous perseverance, in spite of all the incredulity and all the opposition which they meet with. The subject of the communication may be most unpalatable to us; and we be so unreasonable, as

to wreck our unpleasant feelings upon the bearers of it. In this way, they may not only have no earthly interest to deceive us, but have the strongest inducement possible to abstain from insisting upon that message which they were charged to deliver. Last of all, as the conclusive seal of their authenticity, they may all agree in giving us a watchword, which we previously knew could be given by none but their master; and which none but his messengers could ever obtain the possession of. In this way, unfruitful as all our efforts may have been upon the first subject of examination, we may derive from the second the most decisive evidence, that the message in question is a real message, and was actually transmitted to us by its professed author.

The case of a message from God.

5. Now, this consideration applies in all its parts to a message from God. The argument for the truth of this message resolves itself into the same two topics of examination. We may sit in judgment upon the subject of the message; or we may sit in judgment upon the credibility of its bearers.

6. The first forms a great part of that argument for the truth of the Christian religion, which comes under the head of its *internal evidences*. The substance of the message is neither more nor less, than that particular scheme of the divine economy which is revealed to us in the New Testament; and the point of inquiry is, whether this scheme be consistent with that knowledge of God and his attributes which we are previously in possession of.

The first way of verifying a message still less applicable to such a case.

7. It appears to us, that no effectual argument can be founded upon this consideration. We are not enough acquainted with the designs or character of the being from whom the message professes to have come. Were the author of the message some distant and unknown individual of our own species, we would scarcely be entitled to found an argument upon any comparison of ours, betwixt the import of the message and the character of the individual, even though we had our general experience of human nature to help us in the speculation. Now, of the invisible God, we have no experience whatever. We are still further removed from all direct and personal observation of him or of his counsels. Whether we think of the eternity of his government, or the mighty range of its influence over the wide departments of nature and of providence, he stands at such a distance from us, as to make the management of his empire a subject inaccessible to all our faculties.

But the second way applicable to it in all its parts

8. It is evident, however, that this does not apply to the second topic of examination. The bearers of the message were beings like ourselves; and we can apply our safe and certain experience of man to their conduct and their testimony. We know too little of God, to found any argument upon the coincidence which we conceive to exist betwixt the subject of the message and our previous conceptions of its author. But we may know enough of man to pronounce upon the credibility of the messengers. Had they the manner and physiognomy of honest men? Was their testimony resisted, and did they persevere in it? Had they any interest in fabricating the message; or did they suffer in consequence of this perseverance? Did they suffer to such a degree, as to constitute a satisfying pledge of their integrity? Was there more than one messenger, and did they agree as to the substance of that communication which they made to the world? Did they exhibit any special mark of their office as the messengers of God; such a mark as none but God could give, and none but his approved messengers could obtain the possession of? Was this mark the power of working miracles; and were these miracles so obviously addressed to the senses, as to leave no suspicion of deceit behind them? These are questions which we feel our competency to take up, and to decide upon. They lie within the legitimate boundaries of human observation; and upon the solution of these do we rest the question of the truth of the Christian religion.

How the belief of those who first received the message can be transmitted to posterity.

9. This, then, is the state of the question with those to whom the message was originally addressed. They had personal access to the messengers; and the evidences of their veracity lay before them. They were the eye and ear-witnesses of those facts, which occurred at the commencement of the Christian religion and upon which its credibility rests. What met their observation must have been enough to satisfy them; but we live at the distance of nearly 2000 years, and is there enough to satisfy us? Those facts, which constitute the evidence for Christianity, might have been credible and convincing to them, if they really saw them; but is there any way by which they can be rendered credible and convincing to us, who only read of them? What is the expedient by which the knowledge and belief of the men of other times can be transmitted to posterity? Can we distinguish between a corrupt and a faithful transmission? Have we evidence before us, by which we can ascertain what was the belief of those to whom the message was first communicated? And can the belief which existed in their minds be derived to ours, by our sitting in judgment upon the reasons which produced it?

By written testimony.

10. The surest way in which the belief and knowledge of the men of former ages can be transmitted to their descendants, is through the medium of written testimony; and it is fortunate for us, that the records of the Christian religion are not the only historical documents which have come down to us. A great variety of information has come down to us in this way; and a great part of that information is as firmly believed, and as confidently proceeded upon, as if the thing narrated had happened within the limits of our eye-sight. No man doubts the invasion of Britain by Julius Cæsar; and no man doubts, therefore, that a conviction of the truth of past events may be fairly produced in the mind by the instrumentality of a written memorial. This is the kind of evidence which is chiefly appealed to for the truth of ancient history; and it is counted satisfying evidence for all that part of it which is received and depended upon.

It is upon this that our faith in all ancient history is founded.

11. In laying before the reader, then, the evidence for the truth of Christianity, we do not call his mind to any singular or unprecedented exercise of its faculties. We call him to pronounce upon the credibility of written documents, which profess to have been published at a certain age, and by certain authors. The inquiry involves in it no principle which is not appealed to every day in questions of ordinary criticism. To sit in judgment on the credibility of a written document, is a frequent and familiar exercise of the understanding with literary men. It is fortunate for the human mind, when so interesting a question as its religious faith can be placed under the tribunal of such evidence as it is competent to pronounce upon. It was fortunate for those to whom Christianity (a professed communication from heaven) was first addressed, that they could decide upon the genuineness of the communication by such familiar and everyday principles, as the marks of truth or falsehood in the human bearers of that communication. And it is fortunate for us, that when, after that communication has assumed the form of a historical document, we can pronounce upon the degree of credit which should be at-

tached to it, by the very same exercise of mind which we so confidently engage in, when sitting in examination upon the other historical documents that have come down to us from antiquity.

There is a peculiar impression given to the testimony, when its subject is a fact connected with religion.

12. If two historical documents possess equal degrees of evidence, they should produce equal degrees of conviction. But if the object of the one be to establish some fact connected with our religious faith, while the object of the other is to establish some fact, about which we feel no other interest, than that general curiosity which is gratified by the solution of any question in literature, this difference in the object, produces a difference of effect in the feelings and tendencies of the mind. It is impossible for the mind, while it enquires into the evidence of a Christian document, to abstain from all reference to the important conclusion of the enquiry. And this will necessarily mingle its influence with the arguments which engage its attention. It may be of importance to attend to the peculiar feelings which are thus given to the investigation, and in how far they have affected the impression of the Christian argument.

It may lead some to over rate the strength of the testimony,

13. We know it to be the opinion of some, that in this way an undue advantage has been given to that argument. Instead of a pure question of truth, it has been made a question of sentiments, and the wishes of the heart have mingled with the exercise of the understanding. There is a class of men who may feel disposed to overrate its evidences, because they are anxious to give every support and stability to a system, which they conceive to be most intimately connected with the dearest hopes and wishes of humanity; because their imagination is carried away by the sublimity of its doctrines, or their heart engaged by that amiable morality which is so much calculated to improve and adorn the face of society.

14. Now, we are ready to admit, that as the object of the inquiry is not the character, but the truth of Christianity, the philosopher should be careful to protect his mind from the delusion of its charms; he should separate the exercise of the understanding from the tendencies of the fancy or of the heart. He should be prepared to follow the light of evidence, though it may lead him to conclusions the most painful and melancholy. He should train his mind to all the hardihood of abstract and unfeeling intelligence. He should give up every thing to the supremacy of argument, and be able to renounce, without a sigh, all the tenderest prepossessions of infancy, the moment that truth demands of him the sacrifice. Let it be remembered, however, that while one species of prejudice operates in favour of Christianity, another prejudice operates against it. There is a class of men who are repelled from the investigation of its evidences, because in their minds Christianity is allied with the weakness of superstition; and they feel that they are descending, when they bring down their attention to a subject which engrosses so much respect and admiration from the vulgar.

and others to underrate it;

but, upon the whole, it is unfavourable.

15. It appears to us, that the peculiar feeling which the sacredness of the subject gives to the enquirer, is unfavourable to the impression of the Christian argument. Had the subject not been sacred, and had the same testimony been given to the facts that are connected with it, we are satisfied, that the history of Jesus in the New Testament, would have been looked upon as the best supported by evidence of any history that has come down to us. It would assist us in appreciating the evidence for the truth of the gospel history, if we could conceive for a moment, that Jesus, instead of being the founder of a new religion, had been merely the founder of a new school of philosophy, and that the different histories which have come down to us, had merely represented him as an extraordinary person, who had rendered himself illustrious among his countrymen by the wisdom of his sayings, and the beneficence of his actions. We venture to say, that had this been the case, a tenth part of the testimony which has actually been given, would have been enough to satisfy us. Had it been a question of mere erudition, where neither a predilection in favour of a religion, nor an antipathy against it, could have impressed a bias in any one direction, the testimony, both in weight and in quantity, would have been looked upon as quite unexampled in the whole compass of ancient literature.

16. To form a fair estimate of the strength and decisiveness of the Christian argument, we should, if possible, divest ourselves of all reference to religion, and view the truth of the gospel history, purely as a question of erudition. If at the outset of the investigation we have a prejudice against the Christian religion, the effect is obvious; and without any refinement of explanation, we see at once how such a prejudice must dispose us to annex suspicion and distrust to the testimony of the Christian writers. But even when the prejudice is on the side of Christianity, the effect is unfavourable on a mind that is at all scrupulous about the rectitude of its opinions. In these circumstances, the mind gets suspicious of itself. It feels a predilection, and becomes apprehensive lest this predilection may have disposed it to cherish a particular conclusion, independently of the evidences by which it is supported. Were it a mere speculative question, in which the interests of man, and the attachments of his heart, had no share, he would feel greater confidence in the result of his investigation. But it is difficult to separate the moral impressions of piety, and it is no less difficult to calculate their precise influence on the exercises of the understanding. In the complex sentiment of attachment and conviction, which he annexes to the Christian religion, he finds it difficult to say, how much is due to the tendencies of the heart, and how much is due to the pure and unmingled influence of argument. His very anxiety for the truth, disposes him to narrate the circumstances which give a bias to his understanding, and through the whole process of the enquiry, he feels a suspicion and an embarrassment, which he would not have felt, had it been a question of ordinary erudition.

17. The same suspicion which he attaches to himself, he will be ready to attach to all whom he conceives to be in similar circumstances. Now, every author who writes in defence of Christianity is supposed to be a Christian; and this, in spite of every argument to the contrary, has the actual effect of weakening the impression of his testimony. This suspicion affects, in a more remarkable degree, the testimony of the first writers on the side of Christianity. In opposition to it, you have no doubt, to allege the circumstances under which the testimony was given; the tone of sincerity which runs through the performance of the author, the concurrence of other testimonies; the persecutions which were sustained in adhering to them, and which can be accounted for on no other principle, than the power of conscience and conviction; and the utter impossibility of imposing a false testimony on the world, had they even been disposed to do it. Still there is a lurking suspicion, which often survives all this strength of argument, and which it is difficult to get rid of, even after it has been demonstrated to be completely unreasonable. He is a Christian. He is one of the party. Am I an infidel? I persist in distrusting the testimony. Am I a Christian? I rejoice in the strength of it; but this very joy becomes matter of sus-

picion to a scrupulous enquirer. He feels something more than the concurrence of his belief in the testimony of the writer. He catches the infection of his piety and his moral sentiments. In addition to the acquiescence of the understanding, there is a *con amore* feeling both in himself, and in his author, which he had rather been without, because he finds it difficult to compute the precise amount of its influence; and the consideration of this restrains him from that clear and decided conclusion, which he would infallibly have landed in, had it been purely a secular investigation.

The very sacredness of the subject, has thrown a disguise over the strength of the Christian testimony.

18. There is something in the very sacredness of the subject, which intimidates the understanding, and restrains it from making the same firm and confident application of its faculties, which it would have felt itself perfectly warranted to do, had it been a question of ordinary history. Had the apostles been the disciples of some eminent philosopher, and the fathers of the church, their immediate successors in the office of presiding over the discipline and instruction of the numerous schools which they had established, this would have given a secular complexion to the argument, which we think would have been more satisfying to the mind, and have impressed upon it a closer and more familiar conviction of the history in question. We should have immediately brought it into comparison with the history of other philosophers, and could not have failed to recognize, that, in minuteness of information, in weight and quantity of evidence, in the concurrence of numerous and independent testimonies, and in the total absence of every circumstance that should dispose us to annex suspicion to the account which lay before us, it far surpassed any thing that had come down to us from antiquity. It so happens, however, that, instead of being the history of a philosopher, it is the history of a prophet. The veneration we annex to the sacredness of such a character, mingles with our belief in the truth of his history. From a question of simple truth, it becomes a question in which the heart is interested; and the subject from that moment assumes a certain holiness and mystery, which veils the strength of the argument, and takes off from that familiar and intimate conviction which we annex to the far less authenticated histories of profane authors.

And however strong an argument may be, the mere fact of its being much questioned, leaves a feeling that it is very questionable.

19. It may be further observed, that every part of the Christian argument has been made to undergo a most severe scrutiny. The same degree of evidence which, in questions of ordinary history, commands the easy and universal acquiescence of every inquirer, has, in the subject before us, been taken most thoroughly to pieces, and pursued, both by friends and enemies, into all its ramifications. The effect of this is unquestionable. The genuineness and authenticity of the profane historian, are admitted upon much inferior evidence to what we can adduce for the different pieces which make up the New Testament: And why? because the evidence has been hitherto thought sufficient, and the genuineness and authenticity have never been questioned. Not so with the gospel history. Though its evidence is precisely the same in kind, and vastly superior in degree to the evidence for the history of the profane writer, its evidence has been questioned, and the very circumstance of its being questioned has annexed a suspicion to it. At all points of the question, there has been a struggle and a controversy. Every ignorant objection, and every rash and petulant observation, has been taken up and commented upon by the defenders of Christianity. There has at last been so much said about it, that a general feeling of insecurity is apt to accompany the whole investigation. There has been so much fighting, that Christianity is now looked upon as debateable ground. Other books, where the evidence is much inferior, but which have had the advantage of never being questioned, are received as of established authority. It is striking to observe the perfect confidence with which an infidel will quote a passage from an ancient historian. He perhaps does not overrate the credit due to him. But present him with a tabellated and comparative view of all the evidences that can be adduced for the gospel of Matthew, and any profane historian which he chooses to fix upon, and let each distinct evidence be discussed upon no other principle than the ordinary and approved principle of criticism, we assure him that the sacred history would far outweigh the profane in the number and value of its testimonies.

Examples of the above remarks.

20. In illustration of the above remarks, we can refer to the experience of those who have attended to this examination. We ask them to recollect the satisfaction which they felt, when they came to those parts of the examination, where the argument assumes a secular complexion. Let us take the testimony of Tacitus for an example. He asserts the execution of our Saviour in the reign of Tiberius, and under the procuratorship of Pilate; the temporary check which this gave to his religion; its revival, and the progress it had made, not only over Judea, but to the city of Rome. Now all this is attested in the Annals of Tacitus. But it is also attested in a far more direct and circumstantial manner in the annals of another author, in a book entitled the *History of the Acts of the Apostles by the Evangelist Luke.* Both of these performances carry on the very face of them the appearance of unsuspicious and well-authenticated documents. But there are several circumstances, in which the testimony of Luke possesses a decided advantage over the testimony of Tacitus. He was the companion of these very apostles. He was an eye-witness to many of the events recorded by him. He had the advantage over the Roman historian in time and in place, and in personal knowledge of many of the circumstances in his history. The genuineness of his publications, too, and the time of its appearance, are far better established, and by precisely that kind of argument which is held decisive in every other question of erudition. Besides all this, we have the testimony of at least five of the Christian fathers, all of whom had the same, or a greater, advantage in point of time than Tacitus, and who had a much nearer and readier access to original sources of information. Now, how comes it that the testimony of Tacitus, a distant and later historian, should yield such delight and satisfaction to the inquirer, while all the antecedent testimony (which, by every principle of approved criticism, is much stronger than the other,) should produce an impression that is comparatively languid and ineffectual? It is owing, in a great measure, to the principle which we have already alluded to. There is a sacredness annexed to the subject, so long as it is under the pen of fathers and evangelists, and this very sacredness takes away from the freedom and confidence of the argument. The moment that it is taken up by a profane author, the spell which held the understanding in some degree of restraint is dissipated. We now tread on the more familiar ground of ordinary history; and the evidence for the truth of the gospel appears more assimilated to that evidence, which brings home to our conviction the particulars of the Greek and Roman story.

21. To say that Tacitus was upon this subject a disinterested historian, is not enough to explain the preference which you give to his testimony. There is no subject in which the triumph of the Christian argument is more conspicuous, than the moral qualifications which

give credit to the testimony of its witnesses. We have every possible evidence, that there could be neither mistake nor falsehood in their testimony; a much greater quantity of evidence, indeed, than can actually be produced to establish the credibility of any other historian. Now all we ask is, that where an exception to the veracity of any historian is removed, you restore him to that degree of credit and influence which he ought to have possessed, had no such exception been made. In no case has an exception to the credibility of an author been more triumphantly removed, than with the early Christian writers; and yet, as a proof that there really exists some such delusion as we have been labouring to establish, though our eyes are perfectly open to the integrity of the Christian witnesses, there is still a disposition to give the preference to the secular historian. When Tacitus is placed by the side of the evangelist Luke, even after the decisive argument which establishes the credit of the latter historian has convinced the understanding, there remains a tendency in the mind to annex a confidence to the account of the Roman writer, which is altogether disproportioned to the relative merits of his testimony.

22. Let us suppose, for the sake of further illustration, that Tacitus had included some more particulars in his testimony, and that, in addition to the execution of our Saviour, he had asserted, in round and unqualified terms, that this said Christus had risen from the dead, and was seen alive by some hundreds of his acquaintances. Even this would not have silenced altogether the cavils of enemies, but it would have reclaimed many an infidel; been exulted in by many a sincere Christian; and made to occupy a foremost place in many a book upon the evidences of our religion. Are we to forget all the while, that we are in actual possession of much stronger testimony? that we have the concurrence of eight or ten cotemporary authors, most of whom had actually seen Christ after the great event of his resurrection? that the veracity of these authors, and the genuineness of their respective publications, are established on grounds much stronger than have ever been alleged in behalf of Tacitus, or any ancient author? Whence this unaccountable preference of Tacitus? Upon every received principle of criticism, we are bound to annex greater confidence to the testimony of the apostles. It is vain to recur to the imputation of its being an interested testimony. This the apologists for Christianity undertake to disprove, and actually have disproved it, and that by a much greater quantity of evidence than would be held perfectly decisive in a question of common history. If after this there should remain any lurking sentiment of diffidence or suspicion, it is entirely resolvable into some such principle as I have already alluded to. It is to be treated as a mere feeling,—a delusion which should not be admitted to have any influence on the convictions of the understanding.

23. The principle which we have been attempting to expose, is found, in fact, to run through every part of the argument, and to accompany the enquirer through all the branches of the investigation. The authenticity of the different books of the New Testament forms a very important enquiry, wherein the object of the Christian apologist is to prove that they were really written by their professed authors. In proof of this, there is an uninterrupted series of testimony from the days of the apostles; and it was not to be expected, that a point so isoteric to the Christian society could have attracted the attention of profane authors, till the religion of Jesus, by its progress in the world, had rendered itself conspicuous. It is not then till about eighty years after the publication of the different pieces, that we meet with the testimony of Celsus, an avowed enemy to Christianity, and who asserts, upon the strength of its general notoriety, that the historical parts of the New Testament were written by the disciples of our Saviour. This is very decisive evidence. But how does it happen, that it should throw a clearer gleam of light and satisfaction over the mind of the enquirer, than he had yet experienced in the whole train of his investigation? Whence that disposition to underrate the antecedent testimony of the Christian writers? Talk not, of their's being an interested testimony; for, in point of fact, the same disposition operates, after reason is convinced that the suspicion is totally unfounded. What we contend for is, that this indifference to the testimony of the Christian writers implies a dereliction of principles, which we apply with the utmost confidence to all similar enquiries.

24. The effects of this same principle are perfectly discernible in the writings of even our most judicious apologists. We offer no reflection against the worthy and meritorious Lardner, who, in his credibility of the gospel history, presents us with a collection of testimonies which should make every Christian proud of his religion. In his evidence for the authenticity of the different pieces which make up the New Testament, he begins with the oldest of the fathers, some of whom were the intimate companions of the original writers. According to our view of the matter, he should have dated the commencement of his argument from a higher point, and begun with the testimonies of these original writers to one another. In the second Epistle of Peter, there is a distinct reference made to the writings of Paul, and in the Acts of the Apostles, there is a reference made to one of the four gospels. Had Peter, instead of being an apostle, ranked only with the fathers of the church, and had his epistle not been admitted into the canon of scripture; this testimony of his would have had a place in the catalogue, and been counted peculiarly valuable, both for its precision and its antiquity. There is certainly nothing in the estimation he enjoyed, or in the circumstances of his epistle being bound up with the other books of the New Testament, which ought to impair the credit of his testimony. But in effect, his testimony does make a weaker impression on the mind, than a similar testimony from Barnabas, or Clement, or Polycarp. It certainly ought not to do it, and there is a delusion in the preference that is thus given to the latter writers. It is in fact another example of the principle which we have been so often insisting upon. What profane authors are in reference to Christian authors at large, the fathers of the church are in reference to the original writers of the New Testament. In contradiction to every approved principle, we prefer the distant and the later testimony, to the testimony of writers, who carry as much evidence and legitimate authority along with them, and who only differ from others in being nearer the original sources of information. We neglect and undervalue the evidence which the New Testament itself furnishes, and rest the whole of the argument upon the external and superinduced testimony of subsequent authors.

25. A great deal of all this is owing to the manner in which the defence of Christianity has been conducted by its friends and supporters. They have given too much in to the suspicions of the opposite party. They have yielded their minds to the infection of their scepticism, and maintained, through the whole process, a caution and a delicacy which they often carry to an excessive degree; and by which, in fact, they have done injustice to their own arguments. Some of them begin

with the testimony of Tacitus as a first principle, and pursue the investigation upwards, as if the evidence that we collect from the annals of the Roman historian were stronger than that of the Christian writers who flourished nearer the scene of the investigation, and whose credibility can be established on grounds which are altogether independent of his testimony. In this way, they come at last to the credibility of the New Testament writers, but by a lengthened and circuitous procedure. The reader feels as if the arguments were diluted at every step in the process of derivation, and his faith in the gospel history is much weaker than his faith in histories that are far less authenticated. Bring Tacitus and the New Testament to an immediate comparison, and subject them both to the touchstone of ordinary and received principles, and it will be found that the latter leaves the former out of sight in all the marks, and characters, and evidences of an authentic history. The truth of the gospel stands on a much firmer and more independent footing, than many of its defenders would dare to give us any conception of. They want that boldness of argument which the merits of the question entitle them to assume. They ought to maintain a more decided front to their adversaries, and tell them, that, in the New Testament itself—in the concurrence of its numerous, and distant, and independent authors—in the uncontradicted authority which it has maintained from the earliest times of the church—in the total inability of the bitterest adversaries of our religion to impeach its credibility—in the genuine characters of honesty and fairness which it carries on the very face of it, that in these, and in every thing else, which can give validity to the written history of past times, there is a weight and a splendour of evidence, which the testimony of Tacitus cannot confirm, and which the absence of that testimony could not have diminished.

26. If it were necessary, in a court of justice, to ascertain the circumstances of a certain transaction which happened in a particular neighbourhood, the obvious expedient would be to examine the agents and the eye-witnesses of that transaction. If six or eight concurred in giving the same testimony—if there was no appearance of collusion amongst them—if they had the manner and aspect of creditable men—above all, if this testimony were made public, and not a single individual, from the numerous spectators of the transaction alluded to, stept forward to falsify it, then, we apprehend, the proof would be looked upon as complete. Other witnesses might be summoned from a distance to give in their testimony, not of what they saw, but of what they heard upon the subject; but their concurrence, though a happy enough circumstance, would never be looked upon as any material addition to the evidence already brought forward. Another court of justice might be held in a distant country, and years after the death of the original witnesses. It might have occasion to verify the same transaction, and for this purpose might call in the only evidence which it was capable of collecting—the testimony of men who lived after the transaction in question, and at a great distance from the place where it happened. There would be no hesitation, in ordinary cases, about which of the two testimonies ought to be preferred; and the record of the first court could be appealed to by posterity as by far the more valuable document, and far more decisive of the point in controversy. Now, what we complain of, is, that in the instance before us, this principle is reversed. The reports of hearsay witnesses is held in higher estimation than the reports of the original agents and spectators. The most implicit credit is given to the testimony of the distant and later historians, and the testimony of the original witnesses is received with as much distrust as if they carried the marks of villany and imposture upon their foreheads. The genuineness of the first record can be established by a much greater weight and variety of evidence, than the genuineness of the second. Yet all the suspicion that we feel upon this subject annexes to the former; and the apostles and evangelists, with every evidence in their favour which it is in the power of testimony to furnish, are, in fact, degraded from the place which they ought to occupy among the accredited historians of past times.

27. The above observations may help to prepare the enquirer for forming a just and impartial estimate of the merits of the Christian testimony. His great object should be to guard against every bias of the understanding. The general idea is, that a predilection in favour of Christianity may lead him to overrate the argument. We believe that if every unfair tendency of the mind could be subjected to a rigorous computation, it would be found that the combined operation of them all has the effect of impressing a bias in a contrary direction. All we wish for, is, that the arguments which are held decisive in other historical questions, should not be looked upon as nugatory when applied to the investigation of those facts which are connected with the truth and establishment of the Christian religion, that every prepossession should be swept away, and room left for the understanding to expatiate without fear, and without incumbrance.

Division of the argument into four points.

28. The argument for the truth of the different facts recorded in the gospel history, resolves itself into four parts. In the first, it shall be our object to prove, that the different pieces which make up the New Testament, were written by the authors whose names they bear, and at the age which is commonly assigned to them. In the second, we shall exhibit the internal marks of truth and honesty which may be gathered from the compositions themselves. In the third, we shall press upon the reader the known situation and history of the authors, as satisfying proofs of the veracity with which they delivered themselves. And, in the fourth part, we shall lay before them the additional and subsequent testimonies, by which the narrative of the original writers is supported.

29. In every point of the investigation, we shall meet with examples of the principle which we have already alluded to. We have said, that if two distinct enquiries be set on foot, where the object of the one is to settle some point of sacred history, and the object of the other is to settle some point of profane history; the mind acquiesces in a much smaller quantity of evidence in the latter case than it does in the former. If this be right, (and to a certain degree it undoubtedly is), then it is incumbent on the defender of Christianity to bring forward a greater quantity of evidence than would be deemed sufficient in a question of common literature, and to demand the acquiescence of his reader upon the strength of this superior evidence. If it be not right beyond a certain degree—and if there be a tendency in the mind to carry it beyond that degree, then this tendency is founded upon a delusion, and it is well that the reader should be apprised of its existence, that he may protect himself from its influence. The superior quantity of evidence which we can bring forward will, in this case, all go to augment the positive effects upon his convictions; and he will rejoice to perceive, that he is far safer in believing what has been handed down to him of the history of Jesus Christ, and the doctrine of his apostles, than in be-

lieving what he has never doubted—the history of Alexander, and the doctrine of Socrates. Could all the marks of veracity, and the list of subsequent testimonies, be exhibited to the eye of the reader in parallel columns, it would enable him, at one glance, to form a complete estimate. We shall have occasion to call his attention to this so often, that we may appear to many of our readers to have expatiated upon our introductory principle to a degree that is tiresome and unnecessary. We conceive, however, that it is the best and most perspicuous way of putting the argument.

The authenticity of the pieces which make up the New Testament.

30. I. The different pieces which make up the New Testament, were written by the authors whose names they bear, and at the time which is commonly assigned to them.

The principles upon which we annex credit to the written memorials of past ages.

31. After the long slumber of the middle ages, the curiosity of the human mind was awakened, and felt its attention powerfully directed to those old writings which have survived the waste of so many centuries. It were a curious speculation to ascertain the precise quantity of evidence which lay in the information of these old documents. And it may help us in our estimate, first to suppose, that in the researches of that period, there was only one composition found which professed to be a narrative of past times. A number of circumstances can be assigned, which might give a certain degree of probability to the information even of this solitary and unsupported document. There is, first, the general consideration, that the principle upon which a man feels himself induced to write a true history, is of more frequent and powerful operation, than the principle upon which a man feels himself induced to offer a false or a disguised representation of facts to the world. This affords a general probability on the side of the document in question being a true narrative; and there may be some particulars connected with the appearance of the performance itself, which might strengthen this probability.

The case supposed of there being only one written memorial of past times.

We may not be able to discover in the story itself any inducement which the man could have in publishing it, if it were mainly and substantially false. We might see an expression of honesty, which it is in the power of written language, as well as of spoken language, to convey. We might see that there was nothing monstrous or improbable in the narrative itself. And, without enumerating every particular calculated to give it the impression of truth, we may, in the progress of our inquiries, have ascertained, that copies of this manuscript were to be found in many places, and in different parts of the world, proving, by the evidence of its diffusion, the general esteem in which it was held by the readers of past ages. This gives us the testimony of these readers to the value of the performance; and as we are supposing it a history, and not a work of imagination, it could only be valued on the principle of its being true information which was laid before them. In this way, a solitary document, transmitted to us from a remote antiquity, might gain credit in the world, though it had been lost sight of for many ages, and only brought to light by the revival of a literary spirit, which had lain dormant during a long period of history.

The supposition extended to two, three, and a greater number.

32. We can farther suppose, that, in the progress of these researches, another manuscript was discovered, having the same characters, and possessing the same separate and original marks of truth with the former. If they both touched upon the same period of history, and gave testimony to the same events, it is plain that a stronger evidence for the truth of these events would be afforded, than what it was in the power of either of the testimonies taken separately to supply. The separate circumstances which gave a distinct credibility to each of the testimonies, are added together, and give a so much higher credibility to those points of information upon which they deliver a common testimony. This is the case when the testimonies carry in them the appearance of being independent of one another. And even when the one is derived from the other, it still affords an accession to the evidence, because the author of the subsequent testimony gives us the distinct assertion, that he believed in the truth of the original testimony.

33. The evidence may be strengthened still farther, by the accession of a third manuscript, and a third testimony. All the separate circumstances which confer credibility upon any one document, even though it stands alone and unsupported by any other, combine themselves into a much stronger body of evidence, when we have obtained the concurrence of several. If, even in the case of a single narrative, a probability lies on the side of its being true, from the multitude and diffusion of copies, and from the air of truth and honesty discernible in the composition itself, the probability is heightened by the coincidence of several narratives, all of them possessing the same claims upon our belief. If it be improbable that one should be written for the purpose of imposing a falsehood upon the world, it is still more improbable that many should be written, all of them conspiring to the same perverse and unnatural objects. No one can doubt, at least, that of the multitude of written testimonies which have come down to us, the true must greatly preponderate over the false; and that the deceitful principle, though it exists sometimes, would never operate to such an extent, as to carry any great or general imposition in the face of all the documents which are before us.

The strong evidence we possess for many points of ancient history.

The supposition must be extended much farther than we have yet carried it, before we reach the degree of evidence and of testimony, which, on many points of ancient history, we are at this moment in actual possession of. Many documents have been collected, professing to be written at different times, and by men of different countries. In this way, a great body of ancient literature has been formed, from which we can collect many points of evidence, too tedious to enumerate. Do we find the express concurrence of several authors to the same piece of history? Do we find, what is still more impressive, events formally announced in one narrative, not told over again, but implied and proceeded upon as true in another? Do we find the succession of history, through a series of ages, supported in a way that is natural and consistent? Do we find these compositions which profess a higher antiquity, appealed to by those which profess a lower? These, and a number of other points, which meet every scholar who betakes himself to the actual investigation, give a most warm and living character of reality to the history of past times. There is a perversity of mind which may resist all this. There is no end to the fancies of scepticism. We may plead in vain the number of written testimonies; their artless coincidence, and the perfect undesignedness of manner by which they often supply the circumstances that serve both to guide and satisfy the inquirer, and to throw light and support upon one another. The infidel will still have something, behind which he can entrench himself; and his last supposition, monstrous and unnatural as it is, may be, that the whole of written history is a laborious fabrication, sustained for many ages, and concurred in by many individuals, with no other purpose than to enjoy the anticipated blunders of the men of future times, whom they had combined with so much dexterity to bewilder and lead astray.

Historical evidence has its true principles.

34. If it were possible to summon up to the presence of the mind, the whole mass of spoken testimony, it would be found that what was false bore a very small proportion to what was true. For many obvious reasons, the proportion of the false to the true must be also small in written testimony. Yet instances of falsehood occur in both; and the actual ability to separate the false from the true in written history, proves that historical evidence has its principles and its probabilities to go upon. There may be the natural signs of dishonesty. There may be the wildness and improbability of the narrative. There may be a total want of agreement on the part of other documents. There may be the silence of every author for ages after the pretended date of the manuscript in question. There may be all these, in sufficient abundance, to convict the manuscript of forgery and falsehood. This has actually been done in several instances. The skill and discernment of the human mind upon the subject of historical evidence, have been improved by the exercise. The few cases in which sentence of condemnation has been given, are so many testimonies to the competency of the tribunal which has sat in judgment over them, and give a stability to their verdict, when any document is approven of. It is a peculiar subject, and the men who stand at a distance from it may multiply their suspicions and their scepticism at pleasure; but no intelligent man ever entered into the details, without feeling the most familiar and satisfying conviction of that credit and confidence, which it is in the power of historical evidence to bestow.

35. Now to apply this to the object of our present division, which is to ascertain the age of the document, and the person who is the author of it. These are points of information which may be collected from the performance itself. They may be found in the body of the composition, or they may be more formally announced in the title-page—and every time that the book is referred to by its title, or the name of the author and age of the publication are announced in any other document that has come down to us, these points of information receive additional proof from the testimony of subsequent writers.

These applied to the determination of past matters of fact.

36. The New Testament is bound up in one volume, but we would be underrating its evidence if we regarded it only as one testimony, and that the truth of the facts recorded in it rested upon the testimony of one historian. It is not one publication, but a collection of several publications, which are ascribed to different authors, and made their first appearance in different parts of the world. To fix the date of their appearance, it is necessary to institute a separate inquiry for each publication; and it is the unexcepted testimony of all subsequent writers, that two of the gospels, and several of the epistles, were written by the immediate disciples of our Saviour, and published in their lifetime. Celsus, an enemy of the Christian faith, refers to the affairs of Jesus as written by his disciples. He never thinks of disputing the fact; and from the extracts which he makes for the purpose of criticism, there can be no doubt in the mind of the reader, that it is one or other of the four gospels to which he refers. The single testimony of Celsus may be considered as decisive of the fact, that the story of Jesus and of his life was actually written by his disciples. Celsus writes about a hundred years after the alleged time of the publication of this story; but that it was written by the companions of this Jesus, is a fact which he never thinks of disputing. He takes it up upon the strength of its general notoriety, and the whole history of that period furnishes nothing that can attach any doubt or suspicion to this circumstance. Referring to a principle already taken notice of, had it been the history of a philosopher instead of a prophet, its authenticity would have been admitted without any formal testimony to that effect. It would have been admitted, so to speak, upon the mere existence of the title-page, combined with this circumstance, that the whole course of history or tradition does not furnish us with a single fact, leading us to believe that the correctness of this title-page was ever questioned. It would have been admitted, not because it was asserted by subsequent writers, but because they made no assertion upon the subject, because they never thought of converting it into a matter of discussion, and because their occasional references to the book in question would be looked upon as carrying in them a tacit acknowledgment, that it was the very same book which it professed to be at the present day. The distinct assertion of Celsus, that the pieces in question were written by the companions of Jesus, though even at the distance of 100 years, is an argument in favour of their authenticity which cannot be alleged for many of the most esteemed compositions of antiquity. It is the addition of a formal testimony to that kind of general evidence, which is founded upon the tacit or implied concurrence of subsequent writers, and which is held to be perfectly decisive in similar cases.

The matters of fact involved in the authenticity of the New Testament, are the times of its appearance and the authors by whom it was written.

The testimony of Celsus to these matters of fact.

The nearer and more valuable testimonies of the Christian writers.

37. Had the pieces, which make up the New Testament, been the only documents of past times, the mere existence of a pretension to such an age, and to such an author, resting on their own information, would have been sustained as a certain degree of evidence, that the real age and the real author had been assigned to them. But we have the testimony of subsequent authors to the same effect; and it is to be remarked, that it is by far the most crowded, and the most closely sustained series of testimonies, of which we have any example in the whole field of ancient history. When we assigned the testimony of Celsus, it is not to be supposed that this is the very first which occurs after the days of the apostles. The blank of a hundred years betwixt the publication of the original story and the publication of Celsus, is filled up by antecedent testimonies, which, in all fairness, should be counted more decisive of the point in question. They are the testimonies of Christian writers, and, in as far as a nearer opportunity of obtaining correct information is concerned, they should be held more valuable than the testimony of Celsus. In some cases, their reference to the books of the new Testament is made in the form of an express quotation, and the author particularly named. In other cases, the quotation is made without reference to the particular author, and ushered in by the general words, "*as it is written*." And besides, there are innumerable allusions to the different parts of the New Testament, scattered over all the writings of the earlier fathers. In this last case, there is no express citation; but we have the sentiment, the term of expression, the very words of the New Testament repeated so often, and by such a number of different writers, as to leave no doubt upon the mind, that they were copied from one common original, which was at that period held in high reverence and estimation. In pursuing the train of references, we do not meet with a single chasm from the days of the original writers. Not to repeat what we have already made some allusion to, the testimonies of the original writers to one another, we proceed to assert, that some of the fathers, whose wri-

tings have come down to us, were the companions of the apostles, and are even named in the books of the New Testament. St Clement, bishop of Rome, is, with the concurrence of all ancient authors, the same whom Paul mentions in his epistle to the Philippians. In his epistle to the church of Corinth, which was written in the name of the whole church of Rome, he refers to the first epistle of Paul to the former church. "Take into your hands the epistle of the blessed Paul the apostle." He then makes a quotation, which is to be found in Paul's first epistle to the Corinthians. Could Clement have done this to the Corinthians themselves, had no such epistle been in existence? And is not this an undoubted testimony, not merely from the mouth of Clement, but on the part of the churches both of Rome and Corinth, to the authenticity of such an epistle? There are in this same epistle of Clement, several quotations of the second kind, which confirm the existence of some other books of the New Testament; and a multitude of allusions or references of the third kind, to the writings of the evangelists, the Acts of the Apostles, and a great many of these epistles which have been admitted into the New Testament. We have similar testimonies from some more of the fathers, who lived and conversed with Jesus Christ. Besides many references of the second and third kind, we have also other instances of the same kind of testimony which Clement gave to St Paul's first epistle to the Corinthians, than which nothing can be conceived more indisputable. Ignatius, writing to the church of Ephesus, takes notice of St Paul's epistle to that church; and Polycarp, an immediate disciple of the apostles, makes the same express reference to St Paul's epistle to the Philippians, in a letter addressed to that people. In carrying our attention down from the apostolical fathers, we follow an uninterrupted series of testimonies to the authenticity of the canonical scriptures. They get more numerous and circumstantial as we proceed,—a thing to be expected from the progress of Christianity, and the greater multitude of writers, who come forward in its defence and illustration.

38. In pursuing the series of writers, from the days of the apostles down to about 150 years after the publication of the pieces which make up the New Testament, we come to Tertullian, of whom Lardner says, "that there are perhaps more and longer quotations of the small volume of the New Testament in this one Christian author, than of all the works of Cicero, though of so uncommon excellence for thought and style, in the writers of all characters for several ages."

The testimony of Christian writers vindicated,

39. We feel ourselves exposed in this part of our investigation, to the suspicion which adheres to every Christian testimony. We have already made some attempts to analyse that suspicion and its ingredients, and we conceive, that the circumstance of the Christians being an interested party, is only one, and not perhaps the principal of these ingredients. At all events, this may be the proper place for disposing of that one ingredient, and for offering a few general observations on the strength of the Christian testimony.

By the sufferings of the writers themselves,

40. In estimating the value of any testimony, there are two distinct subjects of consideration; the person who gives the testimony, and the people to whom the testimony is addressed. It is quite needless to enlarge on the resources which, in the present instance, we derive from both these considerations, and how much each of them contributes to the triumph and solidity of the Christian argument. In as far as the people who give the testimony are concerned, how could they be mistaken in their account of the books of the New Testament, when some of them lived in the same age with the original writers, and were their intimate acquaintances, and when all of them had the benefit of an uncontrolled series of evidence, reaching down from the date of the earliest publications to their own times? Or, how can we suspect that they falsified, when there runs through their writings the same tone of plainness and sincerity, which is allowed to stamp the character of authenticity on other productions; and, above all, when, upon the strength even of heathen testimony, we conclude, that many of them, by their sufferings and death, gave the highest evidence that man can give, of his speaking under the influence of a real and honest conviction?

By the concurrence of the Christian public,

In as far as the people who received the testimony are concerned, to what other circumstances can we ascribe their concurrence, but to the truth of that testimony? In what way was it possible to deceive them upon a point of general notoriety? The books of the New Testament are referred to by the ancient fathers, as writings generally known and respected by the Christians of that period. If they were obscure writings, or had no existence at the time, how can we account for the credit and authority of those fathers who appealed to them, and had the effrontery to insult their fellow Christians by a falsehood so palpable, and so easily detected? Allow them to be capable of this treachery, we have still to explain, how the people came to be the dupes of so glaring an imposition; how they could be permitted to give up every thing for a religion, whose teachers were so unprincipled as to deceive them, and so unwise as to commit themselves upon ground where it was impossible to elude discovery. Could Clement have dared to refer the people of Corinth to an epistle said to be received by themselves, and which had no existence? or, could he have referred the Christians at large to writings which they never heard of? And it was not enough to maintain the semblance of truth with the people of their own party. Where were the Jews all the time? and how was it possible to escape the correction of these keen and vigilant observers?

By the silence of enemies.

We mistake the matter much, if we think, that Christianity at that time was making its insidious way in silence and in secrecy, through a listless and unconcerned public. All history gives an opposite representation. The passions and curiosity of men were quite upon the alert. The popular enthusiasm had been excited on both sides of the question. It had drawn the attention of the established authorities in different provinces of the empire, and the merits of the Christian cause had become a matter of frequent and formal discussion in courts of judicature. If, in these circumstances, the Christian writers had the hardihood to venture upon a falsehood, it would have been upon safer ground than what they naturally adopted. They would never have hazarded to assert what was so open to contradiction, as the existence of books held in reverence among all the churches, and which yet nobody either in or out of these churches ever heard of. They would never have been so unwise as to commit in this way a cause, which had not a single circumstance to recommend it but its truth and its evidences.

41. The falsehood of the Christian testimony on this point, carries along with it a concurrence of circumstances, each of which is the strangest and most unprecedented that ever was heard of. First, That men, who sustained in their writings all the characters of sincerity, and many of whom submitted to martyrdom, as the highest pledge of sincerity which can possibly be given, should have been capable of falsehood at all. Second, That this tendency to falsehood should have been exercised so unwisely, as to appear in an assertion

perfectly open to detection, and which could be so readily converted to the discredit of that religion, which it was the favourite ambition of their lives to promote and establish in the world. Third, That this testimony could have gained the concurrence of the people to whom it was addressed, and that, with their eyes perfectly open to its falsehood, they should be ready to make the sacrifice of life and of fortune in supporting it. Fourth, That this testimony should never have been contradicted by the Jews, and that they should have neglected so effectual an opportunity of disgracing a religion, the progress of which they contemplated with so much jealousy and alarm. Add to this, that it is not the testimony of one writer, which we are making to pass through the ordeal of so many difficulties. It is the testimony of many writers, who lived at different times, and in different countries, and who add the very singular circumstance of their entire agreement with one another, to the other circumstances equally unaccountable, which we have just now enumerated. The falsehood of their united testimony is not to be conceived. It is a supposition which we are warranted to condemn, upon the strength of any one of the above improbabilities taken separately. But the fair way of estimating their effect upon the argument, is to take them jointly, and, in the language of the doctrine of chances, to take the product of all the improbabilities into one another. The argument which this product furnishes for the truth of the Christian testimony, has, in strength and conclusiveness, no parallel in the whole compass of ancient literature.

42. The testimony of Celsus is looked upon as peculiarly valuable, because it is disinterested. But if this consideration gives so much weight to the testimony of Celsus, why should so much doubt and suspicion annex to the testimony of Christian writers, several of whom, before his time, have given a fuller and more express testimony to the authenticity of the gospels? In the persecutions they sustained; in the obvious tone of sincerity and honesty which runs through their writings; in their general agreement upon this subject; in the multitude of their followers, who never could have confided in men that ventured to commit themselves, by the assertion of what was obviously and notoriously false; in the check which the vigilance, both of Jews and Heathens, exercised over every Christian writer of that period; in all these circumstances, they give every evidence of having delivered a fair and unpolluted testimony.

Internal marks of truth in the New Testament.

43. II. We shall now look into the New Testament itself, and endeavour to lay before the reader the internal marks of truth and honesty, which are to be found in it.

The minute accuracy of its allusion to existing manners.

44. Under this head, it may be right to insist upon the minute accuracy, which runs through all its allusions to the existing manners and circumstances of the times. To appreciate the force of this argument, it would be right to attend to the peculiar situation of Judea, at the time of our Saviour. It was then under the dominion of the Roman emperors, and comes frequently under the notice of the profane historians of that period. From this source we derive a great variety of information, as to the manner in which the emperors conducted the government of their different provinces; what degree of indulgence was allowed to the religious opinions of the people, whom they held in subjection; in how far they were suffered to live under the administration of their own laws; the power which was vested in the presidents of provinces; and a number of other circumstances relative to the criminal and civil jurisprudence of that period. In this way, there is a great number of different points in which the historians of the New Testament can be brought into comparison with the secular historians of the age. The history of Christ and his apostles contains innumerable references to the state of public affairs. It is not the history of obscure and unnoticed individuals. They had attracted much of the public attention. They had been before the governors of the country. They had passed through the established forms of justice; and some of them underwent the trial and punishment of the times. It is easy to perceive, then, that the New Testament writers were led to allude to a number of these circumstances in the political history and constitution of the times which came under the cognizance of ordinary historians. This was delicate ground for an inventor to tread upon; and particularly, if he lived at an age subsequent to the time of his history. He might in this case have fabricated a tale, by confining himself to the obscure and familiar incidents of private history; but it is only for a true and a cotemporary historian, to sustain a continued accuracy, through his minute and numerous allusions to the public policy and government of the times.

The extreme delicacy of this test.

45. Within the period of the gospel history, Judea experienced a good many vicissitudes in the state of its government. At one time it formed part of a kingdom under Herod the Great. At another, it formed part of a smaller government under Archelaus. It after this came under the direct administration of a Roman governor, which form was again interrupted for several years, by the elevation of Herod Agrippa to the sovereign power, as exercised by his grandfather; and it is at last left in the form of a province at the conclusion of the evangelical history. There were also frequent changes in the political state of the countries adjacent to Judea; and which are often alluded to in the New Testament. A caprice of the reigning emperor, often gave rise to a new form of government, and a new distribution of territory. It will be readily conceived, how much these perpetual fluctuations in the state of public affairs, both in Judea and its neighbourhood, must add to the power and difficulty of that ordeal to which the gospel history has been subjected.

The coincidence betwixt the writers of the New Testament and Jewish or profane authors.

46. On this part of the subject, there is no want of witnesses with whom to confront the writers of the New Testament. In addition to the Roman writers, who have touched upon the affairs of Judea, we have the benefit of a Jewish historian, who has given us a professed history of his own country. From him, as was to be expected, we have a far greater quantity of copious and detailed narrative, relative to the internal affairs of Judea, to the manners of the people, and those particulars which are connected with their religious belief, and ecclesiastical constitution. With many, it will be supposed to add to the value of his testimony, that he was not a Christian; but that, on the other hand, we have every reason to believe him to have been a most zealous and determined enemy to the cause. It is really a most useful exercise, to pursue the harmony which subsists betwixt the writers of the New Testament, and those Jewish and profane authors, with whom we bring them into comparison. Throughout the whole examination, our attention is confined to forms of justice; successions of governors in different provinces; manners, and political institutions. We are therefore apt to forget the sacredness of the subject; and we appeal to all who have prosecuted this enquiry, if this circumstance is not favourable to their having a closer and more decided impression of the truth of the gospel history. By instituting a comparison betwixt the evangelists and cotemporary authors, and restrict-

ing our attention to these points, which come under the cognizance of ordinary history, we put the apostles and evangelists on the footing of ordinary historians; and it is for those, who have actually undergone the labour of this examination, to tell how much this circumstance adds to the impression of their authenticity. The mind gets emancipated from the peculiar delusion, which attaches to the sacredness of the subject; and which has the undoubted effect of restraining the confidence of its enquiries. The argument assumes a secular complexion, and the writers of the New Testament are restored to that credit, with which the reader delivers himself up to any other historian, who has a much less weight and quantity of historical evidence in his favour.

47. It must be observed, that this opens up to us a field of enquiry, which is by far too extensive for the limits of the present article. We cannot even so much as enter into it, and must restrict ourselves to a few general observations on the nature and precise effect of the argument.

This a strong argument of the antiquity of the writers.

48. In the first place, the accuracy of the numerous allusions to the circumstances of that period, which the gospel history embraces, forms a strong corroboration of that antiquity, which we have already assigned to its writers from external testimony. It amounts to a proof, that it is the production of authors, who lived antecedent to the destruction of Jerusalem, and consequently about the time that is ascribed to them by all the external testimony, which has already been insisted upon. It is that accuracy, which could only be maintained by a cotemporary historian. It would be difficult, even for the author of some general speculation, not to betray his time by some occasional allusion to the ephemeral customs and institutions of the period in which he wrote. But the authors of the New Testament run a much greater risk. There are five different pieces of that collection, which are purely historical, and where there is a continued reference to the characters, and politics, and passing events of the day. The destruction of Jerusalem swept away the whole fabric of Jewish polity, and it is not to be conceived, that the memory of a future generation, could have retained that minute, that varied, that intimate acquaintance with the statistics of a nation no longer in existence, which is evinced in every page of the evangelical writers. We find, in point of fact, that both the Heathen and Christian writers of subsequent ages do often betray their ignorance of the particular customs which obtained in Judea, during the time of our Saviour. And it must be esteemed a strong circumstance in favour of the antiquity of the New Testament, that on a subject, in which the chances of detection are so numerous, and where we can scarcely advance a single step in the narrative without the possibility of betraying our time by some mistaken allusion, it stands distinguished from every later composition in being able to bear the most minute and intimate comparison with the cotemporary historians of that period.

49. The argument derives great additional strength, from viewing the New Testament, not as one single performance, but as a collection of several performances. It is the work of no less than eight different authors, who wrote without any appearance of concert, who published in different parts of the world, and whose writings possess every evidence, both internal and external, of being independent productions. Had only one author exhibited the same minute accuracy of allusion, it would have been esteemed a very strong evidence of his antiquity. But when we see so many authors, exhibiting such a well sustained and almost unexcepted accuracy, through the whole of their varied and distinct narratives; it seems difficult to avoid the conclusion, that they were either the eye-witnesses of their own history, or lived about the period of its accomplishment.

50. When different historians undertake the affairs of the same period, they either derive their information from one another, or proceed upon distinct and independent information of their own. Now, it is not difficult to distinguish the copyist from the original historian. There is something in the very style and manner of an original narrative, which announces its pretensions. It is not possible that any one event, or any series of events, should make such a similar impression upon two witnesses, or dispose them to relate it in the same language, to describe it in the same order, to form the same estimate, as to the circumstances which should be noticed as important, and those other circumstances which should be suppressed as immaterial. Each witness tells the thing in his own way, makes use of his own language, and brings forward circumstances, which the other might omit altogether, as not essential to the purpose of his narrative. It is this agreement in the facts, with this variety in the manner of describing them, that never fails to impress upon the enquirer that additional conviction, which arises from the concurrence of separate and independent testimonies. Now this is precisely that kind of coincidence, which subsists betwixt the New Testament writers and Josephus, in their allusions to the peculiar customs and institutions of that age. Each party maintains the style of original and independent historians. The one often omits altogether, or makes only a slight and distant allusion to what occupies a prominent part in the composition of the other. There is not the slightest vestige of any thing like a studied coincidence betwixt them. There is variety, but no opposition; and it says much for the authenticity of both histories, that the most scrupulous and attentive criticism, can scarcely detect a single example of an apparent contradiction in the testimony of these different authors, which does not admit of a likely, or at least a plausible, reconciliation.

Their substantial, but at the same time unstudied agreement with Josephus.

51. When the difference betwixt two historians is carried to the length of a contradiction, it enfeebles the credit of both their testimonies. When the agreement is carried to the length of a close and scrupulous resemblance in every particular, it destroys the credit of one of the parties, as an independent historian. In the case before us, we neither perceive this difference, nor this agreement. Such are the variations, that, at first sight, the reader is alarmed with the appearance of very serious and embarrassing difficulties. And such is the actual coincidence, that the difficulties vanish, when we apply to them the labours of a profound and intelligent criticism. Had it been the object of the gospel writers to trick out a plausible imposition on the credulity of the world, they would have studied a closer resemblance to the existing authorities of that period; nor would they have laid themselves open to the superficial brilliancy of Voltaire, which dazzles every imagination, and reposed their vindication with the Lelands and Lardners of a distant posterity, whose sober erudition is so little attended to, and which so few know how to appretiate.

Example of an apparent discrepancy.

52. In the gospel, we are told that Herod, the Tetrach of Galilee, married his brother Philip's wife. In Josephus, we have the same story; only he gives a different name to Philip, and calls him Herod; and what adds to the difficulty, there was a Philip of that family, whom we knew not to have been the first husband of Herodias. This is at first sight a little alarming. But, in the progress of our inquiries, we are given to under-

stand from this same Josephus, that there were three Herods in the same family; and therefore, no improbability in there being two Philips. We also know from the histories of that period, that it was quite common for the same individual to have two names; and this is never more necessary, than when employed to distinguish brothers who have one name the same. The Herod who is called Philip, is just as likely a distinction, as the Simon who is called Peter, or the Saul who is called Paul. The name of the high-priest, at the time of our Saviour's crucifixion, was Caiaphas, according to the evangelists. According to Josephus, the name of the high-priest at that period was Joseph. This would have been precisely a difficulty of the same kind, had not Josephus happened to mention, that this Joseph was also called Caiaphas. Would it have been dealing fairly with the evangelists, we ask, to have made their credibility depend upon the accidental omission of another historian? Is it consistent with any acknowledged principle of sound criticism, to bring four writers so entirely under the tribunal of Josephus, each of whom stands as firmly supported by all the evidences which can give authority to an historian; and have greatly the advantage of him in this, that they can add the argument of their concurrence to the argument of each separate and independent testimony? It so happens, however, in the present instance, that even Jewish writers, in their narrative of the same circumstance, give the name of Philip to the first husband of Herodias. We by no means conceive, that any foreign testimony was necessary for the vindication of the evangelists. Still, however, it must go far to dissipate every suspicion of artifice in the construction of their histories. It proved, that, in the confidence with which they delivered themselves up to their own information, they neglected appearance, and felt themselves independent of it. This apparent difficulty, like many others of the same kind, lands us in a stronger confirmation of the honesty of the evangelists; and it is delightful to perceive, how truth receives a fuller accession to its splendour, from the attempts which are made to disgrace and to darken it.

53. On this branch of the argument, the impartial inquirer must be struck with the little indulgence which infidels, and even Christians, have given to the evangelical writers. In other cases, when we compare the narratives of cotemporary historians, it is not expected, that all the circumstances alluded to by one will be taken notice of by the rest; and it often happens, that an event or a custom is admitted upon the faith of a single historian; and the silence of all other writers is not suffered to attach suspicion or discredit to his testimony. It is an allowed principle, that a scrupulous resemblance betwixt two histories is very far from necessary to their being held consistent with one another. And what is more, it sometimes happens, that with cotemporary historians, there may be an apparent contradiction, and the credit of both parties remain as entire and unsuspicious as before. Posterity is in these cases disposed to make the most liberal allowances. Instead of calling it a contradiction, they often call it a difficulty. They are sensible, that, in many instances, a seeming variety of statements has, upon a more extensive knowledge of ancient history, admitted of a perfect reconciliation. Instead, then, of referring the difficulty in question to the inaccuracy or bad faith of any of the parties, they, with more justness and more modesty, refer it to their own ignorance, and to that obscurity which necessarily hangs over the history of every remote age. These principles are suffered to have great influence in every similar investigation; but so soon as, instead of a similar, it becomes a sacred investigation, every ordinary principle is abandoned, and the suspicion annexed to the teachers of religion is carried to the dereliction of all that candour and liberality with which every other document of antiquity is judged of and appreciated. How does it happen, that the authority of Josephus should be acquiesced in as a first principle, while every step, in the narrative of the evangelists, must have foreign testimony to confirm and support it? How comes it, that the silence of Josephus should be construed into an impeachment of the testimony of the evangelists, while it is never admitted for a single moment, that the silence of the evangelists can impart the slightest blemish to the testimony of Josephus? How comes it, that the supposition of two Philips in one family should throw a damp of scepticism over the gospel narrative, while the only circumstance which renders that supposition necessary is the single testimony of Josephus; in which very testimony it is necessarily implied, that there are two Herods in that same family? How comes it, that the evangelists, with as much internal, and a vast deal more of external evidence in their favour, should be made to stand before Josephus, like so many prisoners at the bar of justice? In any other case, we are convinced, that this would be looked upon as *rough handling*. But we are not sorry for it. It has given more triumph and confidence to the argument. And it is no small addition to our faith, that its first teachers have survived an examination, which, in point of rigour and severity, we believe to be quite unexampled in the annals of criticism.

The circumstantiality of the gospel narrative forms another internal evidence in its favour.

54. It is always looked upon as a favourable presumption, when a story is told circumstantially. The art and the safety of an impostor is to confine his narrative to generals, and not to commit himself by too minute a specification of time and place, and allusion to the manners or occurrences of the day. The more of circumstance that we introduce into a story, we multiply the chances of detection, if false; and therefore, where a great deal of circumstance is introduced, it proves, that the narrator feels the confidence of truth, and labours under no apprehension for the fate of his narrative. Even though we have it not in our power to verify the truth of a single circumstance, yet the mere property of a story being circumstantial is always felt to carry an evidence in its favour. It imparts a more familiar air of life and reality to the narrative. It is easy to believe, that the groundwork of a story may be a fabrication; but it requires a more refined species of imposture than we can well conceive, to construct a harmonious and well sustained narrative, abounding in minute and circumstantial details which support one another, and where, with all our experience of real life, we can detect nothing misplaced, or inconsistent, or improbable.

In the first age of Christianity, this circumstance could be verified by immediate observation;

55. To prosecute this argument in all its extent, it would be necessary to present the reader with a complete analysis or examination of the gospel history. But the most superficial observer cannot fail to perceive, that it maintains, in a very high degree, the character of being a circumstantial narrative. When a miracle is recorded, we have generally the name of the town or neighbourhood where it happened; the names of the people concerned; the effect upon the hearts, and convictions of the bye-standers; the arguments and examinations it gave birth to; and all that minuteness of reference and description which impresses a strong character of reality upon the whole history. If we take along with us the time at which this history made its appearance, the argument becomes much stronger. It does not merely carry

a presumption in its favour, from being a circumstantial history: It carries a proof in its favour, because these circumstances were completely within the reach and examination of those to whom it was addressed. Had the evangelists been false historians, they would not have committed themselves upon so many particulars. They would not have furnished the vigilant inquirers of that period with such an effectual instrument for bringing them into discredit with the people; nor foolishly supplied, in every page of their narrative, so many materials for a cross-examination, which would infallibly have disgraced them.

And in the present age, by comparison with cotemporary authors.

Examples.

56. Now, we of this age can institute the same cross-examination. We can compare the evangelical writers with cotemporary authors, and verify a number of circumstances in the history, and government, and peculiar economy of the Jewish people. We therefore have it in our power to institute a cross-examination upon the writers of the New Testament; and the freedom and frequency of their allusions to these circumstances supply us with ample materials for it. The fact, that they are borne out in their minute and incidental allusions by the testimony of other historians, gives a strong weight of what has been called circumstantial evidence in their favour. As a specimen of the argument, let us confine our observations to the history of our Saviour's trial, and execution, and burial. They brought him to Pontius Pilate. We know both from Tacitus and Josephus, that he was at that time governor of Judea. A sentence from him was necessary, before they could proceed to the execution of Jesus; and we know that the power of life and death was usually vested in the Roman governor. Our Saviour was treated with derision; and this we know to have been a customary practice at that time, previous to the execution of criminals, and during the time of it. Pilate scourged Jesus, before he gave him up to be crucified. We know from ancient authors, that this was a very usual practice among the Romans. The account of an execution generally run in this form:—He was stripped, whipped, and beheaded or executed. According to the evangelists, his accusation was written on the top of the cross; and we learn from Suetonius and others, that the crime of the person to be executed was affixed to the instrument of his punishment. According to the evangelists, this accusation was written in three different languages; and we know from Josephus, that it was quite common in Jerusalem to have all public advertisements written in this manner. According to the evangelists, Jesus had to bear his cross; and we know from other sources of information, that this was the constant practice of these times. According to the evangelists, the body of Jesus was given up to be buried at the request of friends. We know that, unless the criminal was infamous, this was the law, or the custom with all Roman governors.

The artless manner in which the circumstances are introduced.

57. These, and a few more particulars of the same kind, occur within the compass of a single page of the evangelical history. The circumstantial manner of the history affords a presumption in its favour, antecedent to all examination into the truth of the circumstances themselves. But it makes a strong addition to the evidence, when we find, that in all the subordinate parts of the main story, the evangelists maintain so great a consistency, with the testimony of other authors, and with all that we can collect from other sources of information, as to the manners and institutions of that period. It is difficult to conceive, in the first instance, how the inventor of a fabricated story would hazard such a number of circumstances, each of them supplying a point of comparison with other authors, and giving to the enquirer an additional chance of detecting the imposition. And it is still more difficult to believe, that truth should have been so artfully blended with falsehood in the composition of this narrative, particularly as we perceive nothing like a forced introduction of any one circumstance. There appears to be nothing out of place, nothing thrust in with the view of imparting an air of probability to the history. The circumstance upon which we bring the evangelists into comparison with profane authors, is often not intimated in a direct form, but in the form of a slight or distant allusion. There is not the most remote appearance of its being fetched or sought for. It is brought in accidentally, and flows in the most natural and undesigned manner out of the progress of the narrative.

The consistency of the gospel narrative.

58. The circumstance, that none of the gospel-writers are inconsistent with one another, falls better under a different branch of the argument. It is enough for our present purpose, that there is no single writer inconsistent with himself. It often happens, that falsehood carries its own refutation along with it; and that, through the artful disguises which are employed in the construction of a fabricated story, we can often detect a flaw or a contradiction, which condemns the authority of the whole narrative. Now, every single piece of the New Testament, wants this mark or character of falsehood. The different parts are found to sustain, and harmonise, and flow out of each other. Each has at least the merit of being a consistent narrative. For any thing we see upon the face of it, it may be true, and a further hearing must be given before we can be justified in rejecting it as the tale of an impostor.

The simple and unostentatious manner of the evangelists.

Their confidence in the integrity of their narrative.

59. There is another mark of falsehood, which each of the gospel narratives appears to be exempted from. There is little or no parading about their own integrity. We can collect their pretensions to credit from the history itself, but we see no anxious display of these pretensions. We cannot fail to perceive the force of that argument, which is derived from the publicity of the Christian miracles, and the very minute and scrupulous examination, which they had to sustain from the rulers, and official men of Judea. But this publicity, and these examinations, are simply recorded by the evangelists. There is no boastful reference to these circumstances, and no ostentatious display of the advantage which they give to the Christian argument. They bring their story forward in the shape of a direct and unencumbered narrative, and deliver themselves with that simplicity and unembarrassed confidence, which nothing but their consciousness of truth and the perfect feeling of their own strength and consistency can account for. They do not write, as if their object was to carry a point that was at all doubtful or suspicious. It is simply to transmit to the men of other times, and of other countries, a memorial of the events which led to the establishment of the Christian religion in the world. In the prosecution of their narrative, we challenge the most refined judge of the human character, to point out a single symptom of diffidence, in the truth of their own story, or of art to cloak this diffidence from the notice of the most severe and vigilant observers. The manner of the New Testament writers does not carry in it the slightest idea of its being a put on manner. It is quite natural, quite unguarded, and free of all apprehension that their story is to meet with any discredit or contradiction from any of those numerous readers, who had it fully in their power to verify or to expose it. We see no expedient made use of to obtain or to conciliate the acquiescence of their readers. They appear to feel as if they did not need it. They deliver what they have to say in a round and un-

varnished manner; nor is it in general accompanied with any of those strong asseverations, by which an impostor so often attempts to practise upon the credulity of his victims.

They betray no apprehension of wonder or incredibility on the part of their readers.

60. In the simple narrative of the evangelists, they betray no feeling of wonder at the extraordinary nature of the events which they record, and no consciousness that what they are announcing is to excite any wonder among their readers. This appears to us, to be a very strong circumstance. Had it been the newly broached tale of an impostor, he would, in all likelihood, have feigned astonishment himself, or at least have laid his account with the doubt and astonishment of those to whom it was addressed. When a person tells a wonderful story to a company who are totally unacquainted with it, he must be sensible, not merely of the surprise which is excited in the minds of the hearers, but of a corresponding sympathy in his own mind with the feelings of those who listen to him. He lays his account with the wonder, if not the incredulity, of his hearers; and this distinctly appears in the terms with which he delivers his story, and the manner in which he introduces it. It makes a wide difference, if, on the other hand, he tells the same story to a company, who have long been apprised of the chief circumstances, but who listen to him for the mere purpose of obtaining a more distinct and particular narrative. Now, in as far as we can collect from the manner of the evangelists, they stand in this last predicament. They do not write, as if they were imposing a novelty upon their readers. In the language of Luke, they write for the sake of giving more distinct information; and that the readers *might know the certainty of those things, wherein they had been instructed.* In the prosecution of this task, they deliver themselves with the most familiar and unembarrassed simplicity. They do not appear to anticipate the surprise of their readers, or to be at all aware, that the marvellous nature of their story is to be any obstacle to its credit or reception in the neighbourhood. At the first performance of our Saviour's miracles, there was a strong and a widely spread sensation over the whole country. *His fame went abroad*, and *all people were amazed.* This is quite natural; and the circumstance of no surprise being either felt or anticipated by the evangelists, in the writing of their history, can best be accounted for by the truth of the history itself, that the experience of years had blunted the edge of novelty, and rendered miracles familiar, not only to them, but to all the people to whom they addressed themselves.

The unity of mind ascribed to JesusChrist.

61. What appears to us a most striking internal evidence for the truth of the gospel, is that perfect unity of mind and of purpose which is ascribed to our Saviour. Had he been an impostor, he could not have foreseen all the fluctuations of his history, and yet no expression of surprise is recorded to have escaped from him. No event appears to have caught him unprepared. We see no shifting of doctrine or sentiment, with a view to accommodate to new or unexpected circumstances. His parables and warnings to his disciples, give sufficient intimation, that he laid his account with all those events, which appeared to his unenlightened friends to be so untoward, and so promising. In every explanation of his objects, we see the perfect consistency of a mind, before whose prophetic eye, all futurity lay open; and when the events of this futurity came round, he met them, not as chances, that were unforeseen, but as certainties which he had provided for. This consistency of his views is supported through all the variations of his history, and it stands finally contrasted in the record of the evangelists, with the misconceptions, the surprises, the disappointments of his followers. The gradual progress of their minds from the splendid anticipations of earthly grandeur, to a full acquiescence in the doctrine of a crucified Saviour, throws a stronger light on the perfect unity of purpose and of conception which animated his, and which can only be accounted for by the inspiration that filled and enlightened it. It may have been possible enough to describe a self-sustained example of this contrast from an actual history before us. It is difficult, however, to conceive, how it could be sustained so well, and in a manner so apparently artless, by means of invention, and particularly when the inventors made their own errors and their own ignorance form part of the fabrication.

The credibility of the first testimonies of the gospel history.

62. III. There was nothing in the situation of the New Testament writers, which leads us to perceive that they had any possible inducement for publishing a falsehood.

The persecution to which the first witnesses were exposed.

63. We have not to allege the mere testimony of the Christian writers, for the danger to which the profession of Christianity exposed all its adherents at that period. We have the testimony of Tacitus to this effect. We have innumerable allusions, or express intimations of the same circumstance in the Roman historians. The treatment and persecution of the Christians makes a principal figure in the affairs of the empire; and there is no point better established in antient history, than that the bare circumstance of being a Christian, brought many to the punishment of death, and exposed all to the danger of a suffering, the most appalling and repulsive to the feelings of our nature.

64. It is not difficult to perceive, why the Roman government, in its treatment of Christians, departed from its usual principles of toleration. We know it to have been their uniform practice, to allow every indulgence to the religious belief of those different countries, in which they established themselves. The truth is, that such an indulgence demanded of them no exertion of moderation or principle. It was quite consonant to the spirit of Paganism. A different country worshipped different gods, but it was a general principle of Paganism, that each country had its gods, to which the inhabitants of that country owed their peculiar homage and veneration. In this way there was no interference betwixt the different religions which prevailed in the world. It fell in with the policy of the Roman government to allow the fullest toleration to other religions, and it demanded no sacrifice of principle. It was even a dictate of principle with them to respect the gods of other countries and the violation of a religion different from their own, seems to have been felt, not merely as a departure from policy or justice, but to be viewed with the same sentiment of horror, which is annexed to blasphemy or sacrilege. So long as we are under Paganism, the truth of one religion does not involve in it the falsehood or rejection of another. In respecting the religion of another country, we did not abandon our own; nor did it follow, that the inhabitants of that other country, annexed any contempt or discredit to the religion in which we had been educated. In this mutual reverence for the religion of each other, no principle was departed from, and no object of veneration abandoned. It did not involve in it the denial, or relinquishment of their own gods, but only the addition of so many more gods to their catalogue.

65. In this respect, however, the Jews stood distinguished from every other people within the limits of the Roman empire. Their religious belief carried in it something more than attachment to their own system. It carried in it the contempt and detestation of every other. Yet, in spite of this circumstance, their religion was protected

by the mild and equitable toleration of the Roman government. The truth is, that there was nothing in the habits or character of the Jews, which was calculated to give much disturbance to the establishments of other countries. Though they admitted converts from other nations, yet their spirit of proselytism was far from being of that active or adventurous kind, which could alarm the Roman government for the safety of any existing institutions. Their high and exclusive veneration for their own system, gave an universal disdain to the Jewish character, which was not at all inviting to foreigners; but still, as it led to nothing mischievous in point of effect, it seems to have been overlooked by the Roman government, as a piece of impotent vanity.

66. But the case was widely different with the Christian system. It did not confine itself to the denial or rejection of every other system. It was for imposing its own exclusive authority over the consciences of all, and for detaching as many as it could from their allegiance to the religion of their own country. It carried on its forehead all the offensive characters of a monopoly, and not merely excited resentment by the supposed arrogance of its pretensions, but from the rapidity and extent of its innovations, spread an alarm over the whole Roman empire for the security of all its establishments. Accordingly, at the commencement of its progress, so long as it was confined to Judea, and the immediate neighbourhood, it seems to have been in perfect safety from the persecutions of the Roman government. It was at first looked upon as a mere modification of Judaism, and that the first Christians differed from the rest of their countrymen, only *in certain questions of their own superstition.* For a few years, after the crucifixion of our Saviour, it seems to have excited no alarm on the part of the Roman emperors, who did not depart from their usual maxims of toleration, till they began to understand the magnitude of its pretensions, and the unlooked for success which attended them.

67. In the course of a very few years, after its first promulgation, it drew down upon it the hostility of the Roman government; and the fact is undoubted, that some of its first teachers, who announced themselves to be the companions of our Saviour, and the eye-winesses of all the remarkable events in his history, suffered martyrdom for their adherence to the religion which they taught.

68. The disposition of the Jews to the religion of Jesus was no less hostile; and it manifested itself at a still earlier stage of the business. The causes of this hostility are obvious to all, who are in the slightest degree conversant with the history of those times. It is true that the Jews did not at all times possess the power of life and death, nor was it competent for them to bring the Christians to execution by the exercise of legal authority. Still, however, their powers of mischief were considerable. Their wishes had always a certain controul over the measures of the Roman governor; and we know, that it was this controul, which was the means of extorting from Pilate the unrighteous sentence by which the very first teacher of our religion was brought to a cruel and ignominious death. We also know, that under Herod Agrippa, the power of life and death was vested in a Jewish sovereign, and that this power was actually exerted against the most distinguished Christians of that time. Add to this, that the Jews had, at all times, the power of inflicting the lesser punishments. They could whip, they could imprison. Besides all this, the Christians had to brave the frenzy of an enraged multitude; and some of them actually suffered martyrdom in the violence of the popular commotions.

69. Nothing is more evident than the utter disgrace which was annexed by the world at large to the profession of Christianity at that period. Tacitus calls it "*superstitio exitiabilis,*" and accuses the Christians of enmity to mankind. By Epictetus and others, their heroism is termed obstinacy, and it was generally treated by the Roman governors as the infatuation of a miserable and despised people. There was none of that glory annexed to it which blazes around the martyrdom of a patriot or a philosopher. That constancy, which, in another cause, would have made them illustrious, was held to be a contemptible folly, which only exposed them to the derision and insolence of the multitude. A name and a reputation in the world might sustain the dying moments of Socrates or Regulus, but what earthly principles can account for the intrepidity of those poor and miserable outcasts, who consigned themselves to a voluntary martyrdom in the cause of their religion?

70. Having premised these observations, we offer the following alternative to the mind of every candid enquirer. The first Christians either delivered a sincere testimony, or they imposed a story upon the world which they knew to be a fabrication.

71. The persecutions to which the first Christians voluntarily exposed themselves, compel us to adopt the first part of the alternative. It is not to be conceived, that a man would resign fortune, and character, and life, in the assertion of what he knew to be a falsehood. The first Christians must have believed their story to be true; and it only remains to prove, that if they believed it to be true, it must be true indeed.

They prove the sincerity of the first witnesses,

72. A voluntary martyrdom must be looked upon as the highest possible evidence which it is in the power of man to give of his sincerity. The martyrdom of Socrates has never been questioned, as an undeniable proof of the sincere devotion of his mind to the principles of that philosophy for which he suffered. The death of Archbishop Cranmer will be allowed by all, to be a decisive evidence of his sincere rejection of what he conceived to be the errors of Popery, and his thorough conviction in the truth of the opposite system. When the council of Geneva burnt Servetus, no one will question the sincerity of the latter's belief, however much he may question the truth of it. Now, in all these cases, the proof goes no further, than to establish the sincerity of the martyr's belief. It goes but a little way indeed, in establishing the justness of it. This is a different question. A man may be mistaken, though he is sincere. His errors, if they are not seen to be such, will exercise all the influence and authority of truth over him. Martyrs have bled on the opposite sides of the question. It is impossible, then, to rest on this circumstance, as an argument for the truth of either system, but the argument is always deemed incontrovertible, in as far as it goes to establish the sincerity of each of the parties, and that both died in the firm conviction of the doctrines which they professed.

And the truth of their testimony.

73. Now the martyrdom of the first Christians, stands distinguished from all other examples by this circumstance, that it not merely proves the sincerity of the martyr's belief; but it also proves, that what he believed was true. In other cases of martyrdom, the sufferer, when he lays down his life, gives his testimony to the truth of an opinion. In the case of the Christians, when they laid down their lives, they gave their testimony to the truth of a fact, of which they affirmed themselves to be the eye and the ear witnesses. The sincerity of both

testimonies is unquestionable; but it is only in the latter case, that the truth of the testimony follows as a necessary consequence of its sincerity. An opinion comes under the cognizance of the understanding, ever liable, as we all know, to error and delusion. A fact comes under the cognizance of the senses, which have ever been esteemed as infallible, when they give their testimony to such plain, and obvious, and palpable appearances, as those which make up the evangelical story. We are still at liberty to question the philosophy of Socrates, or the orthodoxy of Cranmer and Servetus; but if we were told by a Christian teacher, in the solemnity of his dying hour, and with the dreadful apparatus of martyrdom before him, that he saw Jesus after he had risen from the dead; that he conversed with him many days; that he put his hand into the print of his sides; and, in the ardour of his joyful conviction, exclaimed, "My Lord, and my God!" we should feel that there was no truth in the world, if this language and this testimony could deceive us.

74. If Christianity be not true, then the first Christians must have been mistaken as to the subject of their testimony. This supposition is destroyed by the nature of the subject. It was not testimony to a doctrine which might deceive the understanding. It was something more than testimony to a dream, or a trance, or a midnight fancy, which might deceive the imagination. It was testimony to a multitude, and a succession of palpable facts, which could never have deceived the senses, and which preclude all possibility of mistake, even though it had been the testimony only of one individual. But when in addition to this we consider, that it is the testimony, not of one, but of many individuals; that it is a story repeated in a variety of forms, but substantially the same; that it is the concurring testimony of different eye-witnesses, or the companions of eye-witnesses—we may, after this, take refuge in the idea of falsehood and collusion, but it is not to be admitted, that those eight different writers of the New Testament, could have all blundered the matter with such method, and such uniformity.

75. We know that, in spite of the magnitude of their sufferings, there are infidels who, driven from the second part of the alternative, have recurred to the first, and have affirmed, that the glory of establishing a new religion, induced the first Christians to assert, and to persist in asserting, what they knew to be a falsehood. But (though we should be anticipating the last branch of the argument) they forget, that we have the concurrence of two parties to the truth of Christianity, and that it is the conduct only of one of the parties, which can be accounted for by the supposition in question. The two parties are the teachers and the taught. The former may aspire to the glory of founding a new faith; but what glory did the latter propose to themselves from being the dupes of an imposition so ruinous to every earthly interest, and held in such low and disgraceful estimation by the world at large? Abandon the teachers of Christianity to every imputation, which infidelity, on the rack for conjectures to give plausibility to its system, can desire; how shall we explain the concurrence of its disciples? There may be a glory in leading, but we see no glory in being led. If Christianity were false, and Paul had the effrontery to appeal to his 500 living witnesses whom he alleges to have seen Christ after his resurrection; the submissive acquiescence of his disciples remains a very inexplicable circumstance. The same Paul, in his epistles to the Corinthians, tells them that some of them had the gift of healing, and the power of working miracles; and that the sign of an apostle had been wrought among them in wonders and mighty deeds. A man aspiring to the glory of an accredited teacher, would never have committed himself on a subject, where his falsehood could have been so readily exposed. And in the veneration with which we know his epistles to have been preserved by the church of Corinth, we have not merely the testimony of their writer to the truth of the Christian miracles, but the testimony of a whole people who had no interest in being deceived.

76. Had Christianity been false, the reputation of its first teachers lay at the mercy of every individual among the numerous proselytes which they had gained to their system. It may not be competent for an unlettered peasant to detect the absurdity of a doctrine; but he can at all times lift his testimony against a fact, said to have happened in his presence, and under the observation of his senses. Now it so happens, that in a number of the epistles, there are allusions or express intimations of the miracles that had been wrought in the different churches to which these epistles are addressed. How comes it, if it be all a fabrication, that it was never exposed? We know that some of the disciples were driven by the terrors of persecuting violence to resign their profession. How should it happen, that none of them ever attempted to vindicate their apostacy, by laying open the artifice and insincerity of their Christian teachers? We may be sure that such a testimony would have been highly acceptable to the existing authorities of that period. The Jews would have made the most of it; and the vigilant and discerning officers of the Roman government would not have failed to turn it to account. The mystery would have been exposed and laid open, and the curiosity of latter ages would have been satisfied as to the wonderful and unaccountable steps, by which a religion could make such head in the world, though it rested its whole authority on facts; the falsehood of which was accessible to all who were at the trouble to enquire about them. But no! We hear of no such testimony from the apostates of that period. We read of some, who, agonised at the reflection of their treachery, returned to their first profession, and expiated, by martyrdom, the guilt which they felt they had incurred by their dereliction of the truth. This furnishes a strong example of the power of conviction, and when we join with it, that it is conviction in the integrity of those teachers who appealed to miracles which had been wrought among them, it appears to us a testimony in favour of our religion which is altogether irresistible.

The credibility of the subsequent testimonies to the gospel history.

77. IV. But this brings us to the last division of the argument, viz. that the leading facts in the history of the gospel are corroborated by the testimony of others.

The implied testimony of the first converts.

78. The evidence we have already brought forward for the antiquity of the New Testament, and the veneration in which it was held from the earliest ages of the church, is an implied testimony of all Christians to the truth of the gospel history. By proving the authenticity of St Paul's epistles to the Corinthians, we not merely establish his testimony to the truth of the Christian miracles; we establish the additional testimony of the whole church of Corinth, who would never have respected these epistles, if Paul had ventured upon a falsehood so open to detection, as the assertion, that miracles were wrought among them, which not a single individual ever witnessed. By proving the authenticity of the New Testament at large, we secure, not merely that argument which is founded on the testimony and concurrence of those immense multitudes, who in distant countries submitted to the New Testament as the rule of their faith. The tes-

timony of the teachers, whether we take into consideration the subject of that testimony, or the circumstances under which it was delivered, is of itself a stronger argument for the truth of the gospel history than can be alleged for the truth of any other history which has been transmitted down to us from ancient times. The concurrence of the taught carries along with it a host of additional testimonies, which gives an evidence to the evangelical story, that is altogether unexampled. On a point of ordinary history, the testimony of Tacitus is held decisive, because it is not contradicted. The history of the New Testament is not only not contradicted, but confirmed by the strongest possible expressions which men can give of their acquiescence in its truth; by thousands who were either agents or eye-witnesses of the transactions recorded, who could not be deceived, who had no interest, and no glory to gain by supporting a falsehood, and who, by their sufferings in the cause of what they professed to be their belief, gave the highest evidence, that human nature can give of sincerity.

79. In this circumstance, it may be perceived, how much the evidence for Christianity goes beyond all ordinary historical evidence. A profane historian relates a series of events which happen in a particular age; and we count it well, if it be his own age, and if the history which he gives us be the testimony of a cotemporary author. Another historian succeeds him at the distance of years, and by repeating the same story, gives additional evidence of his testimony to its truth. A third historian perhaps goes over the same ground, and lends another confirmation to the history. And it is thus, by collecting all the lights which are thinly scattered over the tract of ages and of centuries, that we obtain all the evidence which can be got, and all the evidence that is generally wished for.

80. Now, there is room for a thousand presumptions, which, if admitted, would overturn the whole of this evidence. For any thing we know, the first historians may have had some interest in disguising the truth, or substituting in its place a falsehood, and a fabrication. True, it has not been contradicted, but they form a very small number of men who feel strongly or particularly interested in a question of history. The literary and speculative men of that age may have perhaps been engaged in other pursuits, or their testimonies may have perished in the wreck of centuries. The second historian may have been so far removed in point of time from the events of his narratives, that he can furnish us not with an independent, but with a derived testimony. He may have copied his account from the original historian, and the falsehood have come down to us in the shape of an authentic and well attested history. Presumptions may be multiplied without end, yet in spite of them, there is a natural confidence in the veracity of man, which disposes us to as firm a belief in many of the facts of antient history, as in the occurrences of the present day.

81. The history of the gospel, however, stands distinguished from all other history, by the uninterrupted nature of its testimony, which carries down its evidence, without a chasm, from its earliest promulgation to the present day. We do not speak of the superior weight and splendour of its evidences, at the first publication of that history, as being supported, not merely by the testimony of one, but by the concurrence of several independent witnesses. We do not speak of its subsequent writers, who, follow one another in a far closer and more crowded train, than there is any other example of in the history or literature of the world. We speak of the strong though unwritten testimony of its numerous proselytes, who, in the very fact of their proselytism, give the strongest possible confirmation to the gospel, and fill up every chasm in the recorded evidence of past times.

The express testimony of subsequent writers.

82. In the written testimonies for the truth of the Christian religion, Barnabas comes next in order to the first promulgators of the evangelical story. He was a cotemporary of the apostles, and writes a very few years after the publication of the pieces which make up the New Testament. Clement follows, who was a fellow labourer of Paul, and writes an epistle in the name of the church of Rome, to the church of Corinth. The written testimonies follow one another with a closeness and a rapidity of which there is no example; but what we insist on at present, is the unwritten and implied testimony of the people who composed these two churches. There can be no fact better established, than that these two churches were planted in the days of the apostles, and that the epistles which were respectively addressed to them, were held in the utmost authority and veneration. There is no doubt, that the leading facts of the gospel history were familiar to them; that it was in the power of many individuals amongst them to verify these facts, either by their own personal observation, or by an actual conversation with eye-witnesses; and that in particular, it was in the power of almost every individual in the church of Corinth, either to verify the miracles which St Paul alludes to, in his epistle to that church, or to detect and expose the imposition, had there been no foundation for such an allusion. What do we see in all this, but the strongest possible testimony of a whole people to the truth of the Christian miracles: there is nothing like this in common history, the formation of a society, which can only be explained by the history of the gospel, and where the conduct of every individual furnishes a distinct pledge and evidence of its truth. And to have a full view of the argument, we must reflect, that it is not one, but many societies scattered over the different countries of the world; that the principle upon which each society was formed, was the divine authority of Christ and his apostles, resting upon the recorded miracles of the New Testament; that these miracles were wrought with a publicity, and at a nearness of time, which rendered them accessible to the enquiries of all, for upwards of half a century; that nothing but the power of conviction could have induced the people of that age to embrace a religion so disgraced and so persecuted; that every temptation was held out for its disciples to abandon it; and that though some of them, overpowered by the terrors of punishment, were driven to apostacy, yet not one of them has left us a testimony which can impeach the miracles of Christianity, or the integrity of its first teachers.

83. It may be observed, that in pursuing the line of continuity from the days of the apostles, the written testimonies for the truth of the Christian miracles follow one another in closer succession, than we have any other example of in antient history. But what gives such peculiar and unprecedented evidence to the history of the gospel, is that in the concurrence of the multitudes who embraced it, and in the existence of those numerous churches and societies of men who espoused the profession of the Christian faith, we cannot but perceive, that every small interval of time betwixt the written testimonies of authors is filled up by materials so strong and so firmly cemented, as to present us with an unbroken chain of evidence, carrying as much authority along with it, as if it had been a diurnal record, commencing from the days of the apostles, and authenticated through its whole progress by the testimony of thousands.

84. Every convert to the Christian faith in these days, gives one additional testimony to the truth of the gospel his-

tory. Is he a Gentile? The sincerity of his testimony is approved by the persecutions, the sufferings, the danger, and often the certainty of martyrdom, which the profession of Christianity incurred. Is he a Jew? The sincerity of his testimony is approved by all these evidences, and in addition to them by this well known fact, that the faith and doctrine of Christianity was in the highest degree repugnant to the wishes and prejudices of that people. It ought never to be forgotten, that in as far as Jews are concerned, Christianity does not owe a single proselyte to its doctrines, but to the power and credit of its evidences, and that Judea was the chief theatre on which these evidences were exhibited. It cannot be too often repeated, that these evidences rest not upon arguments but upon facts, and that the time, and the place, and the circumstance, rendered these facts accessible to the enquiries of all who chose to be at the trouble of this examination. And there can be no doubt that this trouble was taken, whether we reflect on the nature of the Christian faith, as being so offensive to the pride and bigotry of the Jewish people, or whether we reflect on the consequences of embracing it, which were derision, and hatred, and banishment, and death. We may be sure, that a step which involved in it such painful sacrifices, would not be entered into upon light and insufficient grounds. In the sacrifices they made, the Jewish converts gave every evidence of having delivered an honest testimony in favour of the Christian miracles; and when we reflect, that many of them must have been eye-witnesses, and all of them had it in their power to verify these miracles, by conversation and correspondence with bye-standers, there can be no doubt, that it was not merely an honest, but a competent testimony. There is no fact better established, than that many thousands among the Jews believed in Jesus and his apostles; and we have therefore to allege their conversion, as a strong additional confirmation to the written testimony of the original historians.

The objection as to the general infidelity of the Jews considered.

85. One of the popular objections against the truth of the Christian miracles, is the general infidelity of the Jewish people. We are convinced, that at the moment of proposing this objection, an actual delusion exists in the mind of the infidel. In his conception, the Jews and the Christians stand opposed to each other. In the belief of the latter, he sees nothing but a party or an interested testimony, and in the unbelief of the former, he sees a whole people persevering in their antient faith, and resisting the new faith, on the ground of its insufficient evidences. He forgets all the while, that the testimony of a great many of these Christians, is in fact the testimony of Jews. He only attends to them in their present capacity. He contemplates them in the light of Christians, and annexes to them all that suspicion and incredulity which are generally annexed to the testimony of an interested party. He is aware of what they are at present, Christians and defenders of Christianity; but he has lost sight of their original situation, and is totally unmindful of this circumstance, that in their transition from Judaism to Christianity, they have given him the very evidence he is in quest of. Had another thousand of these Jews renounced the faith of their ancestors, and embraced the religion of Jesus, they would have been equivalent to a thousand additional testimonies in favour of Christianity, and testimonies too of the strongest and most unsuspicious kind, that can well be imagined. But this evidence would make no impression on the mind of an infidel, and the strength of it is disguised, even from the eyes of the Christian. These thousand, in the moment of their conversion, lose the appellation of Jews, and merge into the name and distinction of Christians. The Jews, though diminished in number, retain the national appellation; and the obstinacy with which they persevere in the belief of their ancestors, is still looked upon as the adverse testimony of an entire people. So long as one of that people continues a Jew, his testimony is looked upon as a serious impediment in the way of the Christian evidences. But the moment he becomes a Christian, his motives are contemplated with distrust. He is one of the obnoxious and suspected party. The mind carries a reference only to what he is, and not to what he has been. It overlooks the change of sentiment, and forgets, that in the renunciation of old habits, and old prejudices, in defiance to sufferings and disgrace, in attachment to a religion so repugnant to the pride and bigotry of their nation, and above all, in their submission to a system of doctrines which rested its authority on the miracles of their own time, and their own remembrance, every Jewish convert gives the most decisive testimony which man can give for the truth and divinity of our religion.

86. But why then, says the infidel, did they not all believe? Had the miracles of the gospel been true, we do not see how human nature could have held out against an evidence so striking and so extraordinary; nor can we at all enter into the obstinacy of that belief which is ascribed to the majority of the Jewish people, and which led them to shut their eyes against a testimony, that no man of common sense, we think, could have resisted?

87. Many Christian writers have attempted to resolve this difficulty, and to prove that the infidelity of the Jews, in spite of the miracles which they saw, is perfectly consistent with the known principles of human nature. For this purpose, they have enlarged, with much force and plausibility, on the strength and inveteracy of the Jewish prejudices—on the bewildering influence of religious bigotry upon the understanding of men—on the woeful disappointment which Christianity offered to the pride and interests of the nation—on the selfishness of the priesthood—and on the facility with which they might turn a blind and fanatical multitude, who had been trained, by their earliest habits, to follow and to revere them.

88. In the gospel history itself, we have a very consistent account at least of the Jewish opposition to the claims of our Saviour. We see the deeply wounded pride of a nation, that felt itself disgraced by the loss of its independence. We see the arrogance of its peculiar and exclusive claims to the favour of the Almighty. We see the anticipation of a great prince, who was to deliver them from the power and subjection of their enemies. We see their insolent contempt for the people of other countries, and the foullest scorn that they should be admitted to an equality with themselves in the honours and benefits of a revelation from heaven. We may easily conceive, how much the doctrine of Christ and his apostles was calculated to gall, and irritate, and disappoint them; how it must have mortified their national vanity; how it must have alarmed the jealousy of an artful and interested priesthood; and how it must have scandalized the great body of the people, by the liberality with which it addressed itself to all men, and to all nations, and raised to an elevation with themselves, those whom the firmest habits and prejudices of their country had led them to contemplate under all the disgrace and ignominy of outcasts.

89. Accordingly we know, in fact, that bitterness, and resentment, and wounded pride, lay at the bottom of a great deal of the opposition which Christianity experienced from the Jewish people. In the New Testament history itself, we see repeated examples of their outrageous violence, and this is confirmed by the testimony of many other writers. In the history of the martyr-

dom of Polycarp, it is stated, that the Gentiles and Jews inhabiting Smyrna, in a furious rage, and with a loud voice, cried out, "This is the teacher of Asia, the father of the Christians, the destroyer of our gods, who teacheth all men not to sacrifice, nor to worship them!" They collected wood, and the dried branches of trees, for his pile; and it is added, "the Jews also, according to custom, assisting with the greatest forwardness." It is needless to multiply testimonies to a point so generally understood. That it was not conviction alone which lay at the bottom of their opposition to the Christians; that a great deal of passion entered into it; and that their numerous acts of hostility against the worshippers of Jesus, carry in them all the marks of fury and resentment.

90. Now we know that the power of passion will often carry it very far over the power of conviction. We know that the strength of conviction is not in proportion to the quantity of evidence *presented*, but to the quantity of evidence *attended to*, and perceived, in consequence of that attention. We also know, that attention is, in a great measure, a voluntary act, and that it is often in the power of the mind, both to turn away its attention from what would land it in any painful or humiliating conclusion, and to deliver itself up exclusively to those arguments which flatter its taste and its prejudices. All this lies within the range of familiar and every day experience. We all know how much it ensures the success of an argument, when it gets a *favourable* hearing. In by far the greater number of instances, the parties in a litigation are not merely each *attached* to their own side of the question; but each *confident and believing* that theirs is the side on which the justice lies. In these contests of opinion, which take place every day betwixt man and man, and particularly if passion and interest have any share in the controversy, it is evident to the slightest observation, that though it might have been selfishness, in the first instance, which gave a peculiar direction to the understanding, yet each of the parties often comes, at last, to entertain a sincere conviction in the truth of his own argument. It is not that truth is not one and immutable. The whole difference lies in the observers, each of them viewing the object through the medium of his own prejudices, or cherishing those peculiar habits of attention and understanding to which taste or inclination had disposed him.

91. In addition to all this, we know, that though the evidence for a particular truth be so glaring, that it forces itself upon the understanding, and all the sophistry of passion and interest cannot withstand it; yet if this truth be of a very painful and humiliating kind, the obstinacy of man will often dispose him to resist its influence, and, in the bitterness of his malignant feelings, to carry a hostility against it, and that too in proportion to the weight of the argument which may be brought forward in its favour.

92. Now, if we take into account the inveteracy of the Jewish prejudices, and reflect how unpalatable and how mortifying to their pride must have been the doctrine of a crucified Saviour; we believe that their conduct, in reference to Christianity and its miraculous evidences, presents us with nothing anomalous or inexplicable, and that it will appear a possible and a likely thing to every understanding, that has been much cultivated in the experience of human affairs, in the nature of man, and the science of its character and phenomena.

93. There is a difficulty, however, in the way of this investigation. From the nature of the case, it bears no resemblance to any thing else, that has either been recorded in history, or has come within the range of our own personal observation. There is no other example of a people called upon to renounce the darling faith and principles of their country, and that upon the authority of miracles exhibited before them. All the experience we have about the operation of prejudice, and the perversion of the human temper and understanding, cannot afford a complete solution of the question. In many respects, it is a case *sui generis*, and the only creditable information which we can obtain, to enlighten us in this enquiry, is through the medium of that very testimony upon which the difficulty in question has thrown the suspicion that we want to get rid of.

94. Let us give all the weight to this argument of which it is susceptible, and the following is the precise degree in which it affects the merits of the controversy. When the religion of Jesus was promulgated in Judea, its first teachers appealed to miracles wrought by themselves in the face of day, as the evidence of their being commissioned by God. Many adopted the new religion upon this appeal, and many rejected it. An argument in favour of Christianity is derived from the conduct of the first. An objection against Christianity is derived from the conduct of the second. Now, allowing that we are not in possession of experience enough for estimating, in *absolute terms*, the strength of the objection, we propose the following as a solid and unexceptionable principle, upon which to estimate a comparison betwixt the strength of the objection and the strength of the argument. We are sure that the first would not have embraced Christianity had its miracles been false; but we are not sure beforehand, whether the second would have rejected this religion on the supposition of the miracles being true. If experience does not enlighten us as to how far the exhibition of a real miracle would be effectual in inducing men to renounce their old and favourite opinions, we can infer nothing decisive from the conduct of those who still kept by the Jewish religion. This conduct was a matter of uncertainty, and any argument which may be extracted from it cannot be depended upon. But the case is widely different with that party of their nation who were converted from Judaism to Christianity. We know that the alleged miracles of Christianity were perfectly open to examination. We are sure, from our experience of human nature, that in a question so interesting, this examination would be given. We know, from the very nature of the miraculous facts, so remote like every thing from what would be attempted by jugglery, or pretended to by enthusiasm, that, if this examination were given, it would fix the truth or falsehood of the miracles. The truth of these miracles, then, for any thing we know, may be consistent with the conduct of the Jewish party; but the falsehood of these miracles, from all that we do know of human nature, is not consistent with the conduct of the Christian party. Granting that we are *not sure* whether a miracle would force the Jewish nation to renounce their opinions, all that we can say of the conduct of the Jewish party is, that we are not able to explain it. But there is one thing that we *are sure* of. We are sure, that if the pretensions of Christianity be false, it never could have forced any part of the Jewish nation to renounce their opinions, with its alleged miracles, so open to detection, and its doctrines so offensive to every individual. The conduct of the Christian party then is not only what we are able to explain, but we can say with certainty, that it admits of no other explanation, than the truth of that hypothesis which we contend for. We may

not know in how far an attachment to existing opinions will prevail over an argument which is felt to be true; but we are sure, that this attachment will never give way to an argument which is perceived to be false; and particularly when danger, and hatred, and persecution, are the consequences of embracing it. The argument for Christianity, from the conduct of the first proselytes, rests upon the firm ground of experience. The objection against it, from the conduct of the unbelieving Jews, has no experience whatever to rest upon.

95. The conduct of the Jews may be considered as a solitary fact in the history of the world, not from its being an exception to the general principles of human nature, but from its being an exhibition of human nature in singular circumstances. We have no experience to guide us in our opinion as to the probability of this conduct; and nothing, therefore, that can impeach a testimony which all experience in human affairs leads us to repose in as unquestionable. But after this testimony is admitted, we may submit to be enlightened by it; and in the history which it gives us of the unbelieving Jews, it furnishes a curious fact as to the power of prejudice upon the human mind, and a valuable accession to what we before knew of the principles of our nature. It lays before us an exhibition of the human mind in a situation altogether unexampled, and furnishes us with the result of a singular experiment, if we may so call it, in the history of the species. We offer it as an interesting fact to the moral and intellectual philosopher, that a previous attachment may sway the mind even against the impression of a miracle; and those who believe not in the historical evidence which established the authority of Christ and of the apostles, would not believe, even though one rose from the dead.

96. We are inclined to think, that the argument has come down to us in the best possible form, and that it would have been enfeebled by that very circumstance, which the infidel demands as essential to its validity. Suppose for a moment, that we could give him what he wants, that all the priests and people of Judea were so borne down by the resistless evidence of miracles, as by one universal consent to become the disciples of the new religion. What interpretation might have been given to this unanimous movement in favour of Christianity? A very unfavourable one, we apprehend, to the authenticity of its evidences. Will the infidel say, that he has a higher respect for the credibility of those miracles which ushered in the dispensation of Moses, because they were exhibited in the face of a whole people, and gained their unexcepted submission to the laws and the ritual of Judaism? This new revolution would have received the same explanation. We would have heard of its being sanctioned by their prophecies, of its being agreeable to their prejudices, of its being supported by the countenance and encouragement of their priesthood, and that the jugglery of its miracles imposed upon all, because all were willing to be deceived by them. The actual form in which the history has come down, presents us with an argument free of all these exceptions. We, in the first instance, behold a number of proselytes, whose testimony to the facts of Christianity is approved of by what they lost and suffered in the maintenance of their faith; and we, in the second instance, behold a number of enemies, eager, vigilant, and exasperated at the progress of the new religion, who have not questioned the authenticity of our histories, and whose silence, as to the public and widely talked of miracles of Christ and his apostles, we have a right to interpret into the most triumphant of all testimonies.

The infidelity of the uncontroverted Gentiles considered.

97. The same process of reasoning is applicable to the cases of the Gentiles. Many adopted the new religion, and many rejected it. We may not be sure, if we can give an adequate explanation of the conduct of the latter, on the supposition that the evidences are true; but we are perfectly sure, that we can give no adequate explanation of the conduct of the former, on the supposition that the evidences are false. For any thing we know, it is possible that the one party may have adhered to their former prejudices, in opposition to all the force and urgency of argument, which even an authentic miracle carries along with it. But we know that it is not possible that the other party should renounce these prejudices, and that too in the face of danger and persecution, unless the miracles had been authentic. So great is the difference betwixt the strength of the argument and the strength of the objection, that we count it fortunate for the merits of the cause, that the conversions to Christianity were partial. We, in this way, secure all the support which is derived from the inexplicable fact of the silence of its enemies, inexplicable on every supposition, but the undeniable evidence and certainty of the miracles. Had the Roman empire made a unanimous movement to the new religion, and all the authorities of the state lent their concurrence to it, there would have been a suspicion annexed to the whole history of the gospel, which cannot at present apply to it; and from the collision of the opposite parties, the truth has come down to us in a far more unquestionable form than if no such collision had been excited.

98. The silence of Heathen and Jewish writers of that period, about the miracles of Christianity, has been much insisted upon by the enemies of our religion; and has even excited something like a painful suspicion in the breasts of those who are attached to its cause. Certain it is, that no ancient facts have come down to us, supported by a greater quantity of historical evidences, and better accompanied with all the circumstances which can confer credibility on that evidence. When we demand the testimony of Tacitus to the Christian miracles, we forget all the while that we can allege a multitude of much more decisive testimonies; no less than eight cotemporary authors, and a train of succeeding writers, who follow one another with a closeness and a rapidity, of which there is no example in any other department of ancient history. We forget that the authenticity of these different writers, and their pretensions to credit, are founded on considerations, perfectly the same in kind, though much stronger in degree, than what have been employed to establish the testimony of the most esteemed historians of former ages. For the history of the gospel, we behold a series of testimonies, more continuous, and more firmly sustained, than there is any other example of in the whole compass of erudition. And to refuse this evidence, is a proof, that in this investigation, there is an aptitude in the human mind to abandon all ordinary principles, and to be carried away by the delusions which we have already insisted on.

99. But let us try the effect of that testimony which our antagonists demand. Tacitus has actually attested the existence of Jesus Christ; the reality of such a personage; his public execution under the administration of Pontius Pilate; the temporary check which this gave to the progress of his religion; its revival a short time af-

ter his death ; its progress over the land of Judea, and to Rome itself, the metropolis of the empire ;—all this we have in a Roman historian ; and, in opposition to all established reasoning upon these subjects, it is by some more firmly confided in upon his testimony, than upon the numerous and concurring testimonies of nearer and cotemporary writers. But be this as it may, let us suppose that Tacitus had thrown one particular more into his testimony, and that his sentence had run thus : " They had their denomination from Christus, who, in the reign of Tiberius, was put to death as a criminal by the procurator Pontius Pilate, *and who rose from the dead on the third day after his execution, and ascended into heaven.*" Does it not strike every body, that however true the last piece of information may be, and however well established by its proper historians, this is not the place where we can expect to find it ? If Tacitus did not believe the resurrection of our Saviour, (which is probably the case, as he never, in all likelihood, paid any attention to the evidence of a faith which he was led to regard, from the outset, as a pernicious superstition, and a mere modification of Judaism), it is not to be supposed that such an assertion could ever have been made by him. If Tacitus did believe the resurrection of our Saviour, he gives us an example of what appears not to have been uncommon in these ages—he gives us an example of a man adhering to that system which interest and education recommended, in opposition to the evidence of a miracle which he admitted to be true. Still, even on this supposition, it is the most unlikely thing in the world, that he would have admitted the fact of our Saviour's resurrection into his history. It is most improbable, that a testimony of this kind would have been given, even though the resurrection of Jesus Christ be admitted ; and, therefore, the want of this testimony carries in it no argument that the resurrection is a falsehood. If, however, in opposition to all probability, this testimony had been given, it would have been appealed to as a most striking confirmation of the main fact of the evangelical history. It would have figured away in all our elementary treatises, and been referred to as a master argument in every exposition of the evidences of Christianity. Infidels would have been challenged to believe in it on the strength of their own favourite evidence, the evidence of a classical historian ; and must have been at a loss how to dispose of this fact, when they saw an unbiassed heathen giving his round and unqualified testimony in its favour.

100. Let us now carry the supposition a step farther. Let us conceive that Tacitus not only believed the fact, and gave his testimony to it, but that he believed it so far as to become a Christian. Is his testimony to be refused because he gives this evidence of its sincerity ? Tacitus asserting the fact, and remaining a heathen, is not so strong an argument for the truth of our Saviour's resurrection, as Tacitus asserting the fact and becoming a Christian in consequence of it. Yet the moment that this transition is made—a transition by which, in point of fact, it becomes stronger—in point of impression it becomes less ; and, by a delusion, common to the infidel and the believer, the argument is held to be weakened by the very circumstance which imparts greater force to it. The elegant and accomplished scholar becomes a believer. The truth, the novelty, the importance of this new subject, withdraws him from every other pursuit. He shares in the common enthusiasm of the cause, and gives all his talents and eloquence to the support of it. Instead of the Roman historian, Tacitus comes down to posterity in the shape of a Christian father, and the high authority of his name is lost in a crowd of similar testimonies.

101. A direct testimony to the miracles of the New Testament from the mouth of a heathen, is not to be expected. We cannot satisfy this demand of the infidel ; but we can give him a host of much stronger testimonies than he is in quest of—the testimonies of those men who were heathens, and who embraced a hazardous and a disgraceful profession, under a deep conviction of those facts to which they gave their testimony. " O, but you now land us in the testimony of Christians !" This is very true ; but it is the very fact of their being Christians in which the strength of the argument lies : and in each of the numerous fathers of the Christian church, we see a stronger testimony than the required testimony of the heathen Tacitus. We see men who, if they had not been Christians, would have risen to as high an eminence as Tacitus in the literature of the times ; and whose direct testimonies to the gospel history would, in that case, have been most impressive, even to the mind of an infidel. And are these testimonies to be less impressive, because they were preceded by conviction, and sealed by martyrdom ?

102. Yet though, from the nature of the case, no direct testimony to the Christian miracles from a heathen can be looked for, there are heathen testimonies which form an important accession to the Christian argument. Such are the testimonies to the state of Judea, the testimonies to those numerous particulars in government and customs which are so often alluded to in the New Testament, and give it the air of an authentic history. And, above all, the testimonies to the sufferings of the primitive Christians, from which we learn, through a channel clear of every suspicion, that Christianity, a religion of facts, was the object of persecution at a time, when eye-witnesses taught, and eye-witnesses must have bled for it.

103. The silence of Jewish and Heathen writers, when the true interpretation is given to it, is all on the side of the Christian argument. Even though the miracles of the gospel had been believed to be true, it is most unlikely that the enemies of the Christian religion would have given their testimony to them ; and the absence of this testimony is no impeachment therefore upon the reality of these miracles. But if the miracles of the gospel had been believed to be false, it is most likely that this falsehood would have been asserted by the Jews and Heathens of that period ; and the circumstance of no such assertion having been given, is a strong argument for the reality of these miracles. Their silence in not asserting the miracles is perfectly consistent with their truth ; but their silence in not denying them is not at all consistent with their falsehood. The entire silence of Josephus upon the subject of Christianity, though he wrote after the destruction of Jerusalem, and gives us the history of that period in which Christ and his apostles lived, is certainly a very striking circumstance. The sudden progress of Christianity at that time, and the fame of its miracles, (if not the miracles themselves,) form an important part of the Jewish history. How came Josephus to abstain from every particular respecting it ? Will you reverse every principle of criticism, and make the silence of Josephus carry it over the positive testimony of the many historical documents which have come down to us ? If you refuse every Christian testimony upon the subject, you will not refuse the testimony of Tacitus, who asserts, that this religion spread over Judea, and reached the city of Rome, and was looked upon as an evil of such importance, that it became the object of

an authorised persecution by the Roman government; and all this several years before the destruction of Jerusalem, and before Josephus composed his history. Whatever opinion may be formed as to the *truth* of Christianity, certain it is, that its *progress* constituted an object of sufficient magnitude to compel the attention of any historian who undertook the affairs of that period. How then shall we account for the scrupulous and determined exclusion of it from the history of Josephus? Had its miracles been false, this Jewish historian would gladly have exposed them. But its miracles were true, and silence was the only refuge of an antagonist, and his wisest policy.

The indirect testimony of Jews and Gentiles in favour of the gospel history.

104. But though we gather no direct testimony from Josephus, yet his history furnishes us with many satisfying additions to the Christian argument. In the details of policy and manners, he coincides in the main with the writers of the New Testament; and these coincidences are so numerous, and have so undesigned an appearance, as to impress on every person, who is at the trouble of making the comparison, the truth of the evangelical story.

105. If we are to look for direct testimonies to the miracles of the New Testament, we must look to that quarter, where alone it would be reasonable to expect them, to the writings of the Christian fathers, men who were not Jews or Heathens at the moment of recording their testimony; but who had been Jews or Heathens, and who, in their transition to the ultimate state of Christians, give a stronger evidence of integrity, than if they had believed these miracles, and persisted in a cowardly adherence to the safest profession.

106. We do not undertake to satisfy every demand of the infidel. We think we do enough, if we prove that the thing demanded is most unlikely, even though the miracles should be true; and therefore that the want of it carries no argument against the truth of the miracles. But we do still more than this, if we prove that the testimonies which we actually possess are much stronger than the testimonies he is in quest of. And who can doubt this, when he reflects, that the true way of putting the case betwixt the testimony of the Christian father, which we do have, and the testimony of Tacitus, which we do not have, is, that the latter would be an assertion not followed up by that conduct, which would have been the best evidence of its sincerity. Whereas, the former is an assertion substantiated by the whole life, and by the decisive fact of the old profession having been renounced, and the new profession entered into,—a change where disgrace, and danger, and martyrdom were the consequences.

107. Let us, therefore, enter into an examination of these testimonies.

A more particular exposition of the testimonies of the Christian writers.

108. This subject has been in part anticipated, when we treated of the authenticity of the books of the New Testament. We have quotations and references to these books from five apostolic fathers, the companions of the original writers. We have their testimonies sustained and extended by their immediate successors; and as we pursue this crowded series of testimonies downwards, they become so numerous, and so explicit, as to leave no doubt on the mind of the inquirers, that the different books of the New Testament are the publications of the authors, whose names they bear; and were received by the Christian world, as books of authority from the first period of their appearance.

109. Now, every sentence in a Christian father, expressive of respect for a book in the New Testament, is also expressive of his faith in its contents. It is equivalent to his testimony for the miracles recorded in it. In the language of the law, it is an act by which he homologates the record, and superinduces his own testimony to that of the original writers. It would be vain to attempt speaking of all these testimonies. It cost the meritorious Lardner many years to collect them. They are exhibited in his credibility of the new Testament; and in the multitude of them, we see a power and a variety of evidence for the Christian miracles, which is quite unequalled in the whole compass of ancient history.

110. But, in addition to these testimonies in the gross, for the truth of the evangelical history, have we no distinct testimonies to the individual facts which compose it? We have no doubt of the fact, that Barnabas was acquainted with the gospel by Matthew, and that he subscribed to all the information contained in that history. This is a most valuable testimony from a cotemporary writer; and a testimony which embraces all the miracles narrated by the evangelist. But, in addition to this, we should like if Barnabas, upon his own personal conviction, could assert the reality of any of these miracles. It would be multiplying the original testimonies; for he was a companion and a fellow-labourer of the apostles. We should have been delighted, if, in the course of our researches into the literature of past times, we had met with an authentic record, written by one of the five hundred, that are said to have seen our Saviour after his resurrection, and adding his own narrative of this event to the narratives that have already come down to us. Now, is any thing of this kind to be met with in ecclesiastical antiquity? How much of this kind of evidence are we in actual possession of? and if we have not enough to satisfy our keen appetites for evidence on a question of such magnitude, how is the want of it to be accounted for?

111. Let it be observed, then, that of the twenty-seven books which make up the New Testament, five are narrative or historical, viz. the four Gospels, and the Acts of the Apostles, which relate to the life and miracles of our Saviour, and the progress of his religion through the world, for a good many years after his ascension into heaven. All the rest, with the exception of the gospel by St John, are doctrinal or admonitory; and their main object is to explain the principles of the new religion, or to impress its duties upon the numerous proselytes who had even at that early period been gained over to the profession of Christianity.

112. Besides what we have in the New Testament, no other professed narrative of the miracles of Christianity has come down to us, bearing the marks of an authentic composition by any apostle, or any cotemporary of the apostles. Now, to those who regret this circumstance, we beg leave to submit the following observations. Suppose that one other narrative of the life and miracles of our Saviour had been composed, and, to give all the value to this additional testimony of which it is susceptible, let us suppose it to be the work of an apostle. By this last circumstance, we secure to its uttermost extent the advantage of an original testimony, the testimony of another eye-witness, and constant companion of our Saviour. Now, we ask, what would have been the fate of this performance? It would have been incorporated into the New Testament along with the other gospels. It may have been the gospel according to Philip. It may have been the gospel according to Bartholomew. At all events, the whole amount of the advantage would have been, the substitution of five gospels instead of four, and this addition, the want of which is so much complained

of, would scarcely have been felt by the Christians, or acknowledged by the infidel to strengthen the evidence which we are already in possession of.

113. But to vary the supposition, let us suppose that the narrative wanted, instead of being the work of an apostle, had been the work of some other cotemporary, who writes upon his own original knowledge of the subject, but was not so closely associated with Christ, or his immediate disciples, as to have his history admitted in the canonical scriptures. Had this history been preserved, it would have been transmitted to us in a separate state, it would have stood out from among that collection of writings, which passes under the general name of the New Testament, and the additional evidence thus afforded, would have come down in the form most satisfactory to those with whom we are maintaining our present argument. Yet though, in point of form, the testimony might be more satisfactory; in point of fact, it would be less so. It is the testimony of a less competent witness,—a witness who, in the judgment of his cotemporaries, wanted those accomplishments which entitled him to a place in the New Testament. There must be some delusion operating upon the understanding, if we think that a circumstance, which renders an historian less accredited in the eyes of his own age, should render him more accredited in the eyes of posterity. Had Mark been kept out of the New Testament, he would have come down to us in that form, which would have made his testimony more impressive to a superficial enquirer; yet there would be no good reason for keeping him out, but precisely that reason which should render his testimony less impressive. We do not complain of this anxiety for more evidence, and as much of it as possible; but it is right to be told, that the evidence we have is of far more value than the evidence demanded, and that, in the concurrence of four canonical narratives, we see a far more effectual argument for the miracles of the New Testament, than in any number of those separate and extraneous narratives, the want of which is so much felt, and so much complained of.

114. That the New Testament is not one, but a collection of many testimonies, is what has been often said, and often acquiesced in. Yet even after the argument is formally acceded to, its impression is unfelt; and on this subject there is a great and an obstinate delusion, which not only confirms the infidel in his disregard to Christianity, but even veils the strength of the evidence from its warmest admirers.

115. There is a difference betwixt a mere narrative and a work of speculation or morality. The latter subjects embrace a wider range, admit a greater variety of illustration, and are quite endless in their application to the new cases that occur in the ever-changing history of human affairs. The subject of a narrative again admits of being exhausted. It is limited by the number of actual events. True, you may expatiate upon the character or importance of these events, but, in so doing, you drop the office of the pure historian, for that of the politician, or the moralist, or the divine. The evangelists give us a very chaste and perfect example of the pure narrative. They never appear in their own persons, or arrest the progress of the history for a single moment, by interposing their own wisdom, or their own piety. A gospel is a bare relation of what has been said or done; and it is evident that, after a few good compositions of this kind, any future attempts would be superfluous and uncalled for.

116. But, in point of fact, these attempts were made. It is to be supposed, that, after the singular events of our Saviour's history, the curiosity of the public would be awakened, and there would be a demand for written accounts of such wonderful transactions. These written accounts were accordingly brought forward. Even in the interval of time betwixt the ascension of our Saviour, and the publication of the earliest gospel, such written histories seem to have been frequent. "Many," says St Luke, (and in this he is supported by the testimony of subsequent writers,) "have taken in hand to set forth in order a declaration of these things." Now what has been the fate of all these performances? Such as might have been anticipated. They fell into disuse and oblivion. There is no evil design ascribed to the authors of them. They may have been written with perfect integrity, and been useful for a short time, and within a limited circle; but, as was natural, they all gave way to the superior authority, and more complete information of our present narratives. The demand of the Christian world was withdrawn from the less esteemed, to the more esteemed histories of our Saviour. The former ceased to be read, and copies of them would be no longer transcribed or multiplied. We cannot find the testimony we are in quest of, not because it was never given, but because the early Christians, who were the most competent judges of that testimony, did not think it worthy of being transmitted to us.

117. But, though the number of narratives be necessarily limited by the nature of the subject, there is no such limitation upon works of a moral, didactic, or explanatory kind. Many such pieces have come down to us, both from the apostles themselves, and from the earlier fathers of the church. Now, though the object of these compositions is not to deliver any narrative of the Christian miracles, they may perhaps give us some occasional intimation of them, they may proceed upon their reality. We may gather either from incidental passages, or from the general scope of the performance, that the miracles of Christ and his apostles were recognised, and the divinity of our religion acknowledged, as founded upon these miracles.

118. The first piece of the kind which we meet with, besides the writings of the New Testament, is an epistle ascribed to Barnabas, and, at all events, the production of a man, who lived in the days of the apostles. It consists of an exhortation to constancy in the Christian profession, a dissuasive from Judaism, and other moral instructions. We shall only give a quotation of a single clause from this work. "And he (i. e. our Saviour) making great signs and prodigies to the people of the Jews, they neither believed nor loved him."

119. The next piece in the succession of Christian writers, is the undoubted epistle of Clement, the bishop of Rome, to the church of Corinth, and who, by the concurrent voice of all antiquity, is the same Clement who is mentioned in the epistle to the Philippians, as the fellow-labourer of Paul. It is written in the name of the church of Rome, and the object of it is to compose certain dissensions which had arisen in the church of Corinth. It was out of his way to enter into any thing like a formal narrative of the miraculous facts which are to be found in the evangelical history. The subject of his epistle did not lead him to this; and besides, the number and authority of the narratives already published, rendered an attempt of this kind altogether superfluous. Still, however, though a miracle may not be formally announced, it may be brought in incidentally, or it may be proceeded upon, or assumed as the basis of an argument. We give one or two examples of this. In one part of his epistle, he illustrates the doctrine of our resurrection from the

dead, by the change and progression of natural appearances, and he ushers in this illustration with the following sentence: "Let us consider, my beloved, how the Lord shows us our future resurrection perpetually, of which he made the Lord Jesus Christ the first fruits, by raising him from the dead." This incidental way of bringing in the fact of our Lord's resurrection, appears to us the strongest possible form in which the testimony of Clement could have come down to us. It is brought forward in the most confident and unembarrassed manner. He does not stop to confirm this fact by any strong asseveration, nor does he carry, in his manner of announcing it, the most remote suspicion of its being resisted by the incredulity of those to whom he is addressing himself. It wears the air of an acknowledged truth, a thing understood and acquiesced in by all the parties in this correspondence. The direct narrative of the evangelists gives us their original testimony to the miracles of the gospel. The artless and indirect allusions of the apostolic fathers, give us not merely their faith in this testimony, but the faith of the whole societies to which they write. They let us see, not merely that such a testimony was given, but that such a testimony was generally believed, and that too at a time when the facts in question lay within the memory of living witnesses.

120. In another part, speaking of the apostles, Clement says, that "receiving the commandments, and being filled with full certainty by the resurrection of Jesus Christ, and confirmed by the word of God, with the assurance of the Holy Spirit, they went out announcing the advent of the kingdom of God."

121. It was no object, in those days, for a Christian writer to come over the miracles of the New Testament, with the view of lending his formal and explicit testimony to them. This testimony had already been completed to the satisfaction of the whole Christian world. If much additional testimony has not been given, it is because it was not called for. But we ought to see, that every Christian writer, in the fact of his being a Christian, in his expressed reverence for the books of the New Testament, and in his numerous allusions to the leading points of the gospel history, has given as satisfying evidence to the truth of the Christian miracles, as if he had left behind him a copious and distinct narrative.

122. Of all the miracles of the gospel, it was to be supposed, that the resurrection of our Saviour would be oftenest appealed to; not as an evidence of his being a teacher,—for that was a point so settled in the mind of every Christian, that a written exposition of the argument was no longer necessary,—but as a motive to constancy in the Christian profession, and as the great pillar of hope in our own immortality. We accordingly meet with the most free and confident allusions to this fact in the early fathers. We meet with five intimations of this fact in the undoubted epistle of Polycarp to the Philippians: a father who had been educated by the apostles, and conversed with many who had seen Christ.

123. It is quite unnecessary to exhibit passages from the epistles of Ignatius to the same effect, or to pursue the examination downwards through the series of written testimonies. It is enough to announce it as a general fact, that, in the very first age of the Christian church, the teachers of this religion proceeded as confidently upon the reality of Christ's miracles and resurrection in their addresses to the people, as the teachers of the present day: Or, in other words, that they were as little afraid of being resisted by the incredulity of the people, at a time when the evidence of the facts was accessible to all, and habit and prejudice were against them, as we are of being resisted by the incredulity of an unlettered multitude, who listen to us with all the veneration of a hereditary faith.

124. There are five apostolic fathers, and a series of Christian writers who follow after them in rapid succession. To give an idea to those who are not conversant in the study of ecclesiastical antiquities, how well sustained the chain of testimony is from the first age of Christianity, we shall give a passage from a letter of Irenæus, preserved by Eusebius. We have no less than nine compositions from different authors, which fill up the interval betwixt him and Polycarp; and yet this is the way in which he speaks, in his old age, of the venerable Polycarp, in a letter to Florinus. "I saw you, when I was very young, in the Lower Asia with Polycarp. For I better remember the affairs of that time than those which have lately happened: the things which we learn in our childhood growing up in the soul, and uniting themselves to it. Insomuch, that I can tell the place in which the blessed Polycarp sat and taught, and his going out, and coming in, and the manner of his life, and the form of his person, and his discourses to the people; and how he related his conversation with John, and others who had seen the Lord; and how he related their sayings, and what he had heard from them concerning the Lord, both concerning his miracles and his doctrines, as he had received them from the eye-witnesses of the Word of Life: all which Polycarp related agreeably to the Scriptures. These things I then, through the mercy of God toward me, diligently heard and attended to, recording them not on paper, but upon my heart."

They lead the mind back to the number and weight of the original testimonies.

125. Now is the time to exhibit to full advantage the argument which the different epistles of the New Testament afford. They are, in fact, so many distinct and additional testimonies. If the testimonies drawn from the writings of the Christian fathers are calculated to make any impression, then the testimonies of these epistles, where there is no delusion, and no prejudice in the mind of the inquirer, must make a greater impression. They are more ancient, and were held to be of greater authority by competent judges. They were held sufficient by the men of these days, who were nearer to the sources of evidence; and they ought, therefore, to be held sufficient by us. The early persecuted Christians had too great an interest in the grounds of their faith, to make a light and superficial examination. We may safely commit the decision to them; and the decision they have made, is, that the authors of the different epistles in the New Testament, were worthier of their confidence, as witnesses of the truth, than the authors of those compositions which were left out of the collection, and maintain, in our eye, the form of a separate testimony. By what unaccountable tendency is it, that we feel disposed to reverse this decision, and to repose more faith in the testimony of subsequent and less esteemed writers? Is there any thing in the confidence given to Peter and Paul by their cotemporaries, which renders them unworthy of ours? or, is the testimony of their writings less valuable and less impressive, because the Christians of old have received them as the best vouchers of their faith?

126. It gives us a far more satisfying impression than ever of the truth of our religion, when, in addition to several distinct and independent narratives of its history, we meet with a number of contemporaneous productions addressed to different societies, and all proceeding upon the truth of that history, as an agreed and unquestionable point amongst the different parties in the correspondence. Had that history been a fabrication, in what manner, we

ask, would it have been followed up by the subsequent compositions of those numerous agents in the work of deception? How comes it, that they have betrayed no symptom of that insecurity which it would have been so natural to feel in their circumstances? Through the whole of these epistles, we see nothing like the awkward or embarrassed air of an impostor. We see no anxiety, either to mend or to confirm the history that had already been given. We see no contest which they might have been called upon to maintain with the incredulity of their converts, as to the miracles of the gospel. We see the most intrepid remonstrance against errors of conduct, or discipline, or doctrine. This savours strongly of upright and independent teachers; but is it not a most striking circumstance, that, amongst the severe reckonings which St Paul had with some of his churches, he was never once called upon to school their doubts, or their suspicions, as to the reality of the Christian miracles? This is a point universally acquiesced in; and, from the general strain of these epistles, we collect, not merely the testimony of their authors, but the unsuspected testimony of all to whom they addressed themselves.

127. And let it never be forgotten, that the Christians who composed these churches, were in every way well qualified to be arbiters in this question. They had the first authorities within their reach. The five hundred who, Paul says to them, had seen our Saviour after his resurrection, could be sought after; and if not to be found, Paul would have had his assertion to answer for. In some cases, they were the first authorities themselves, and had therefore no confirmation to go in search of. He appeals to the miracles which had been wrought among them, and in this way he commits the question to their own experience. He asserts this to the Galatians; and at the very time, too, that he is delivering against them a most severe and irritating invective. He intimates the same thing repeatedly to the Corinthians; and after he had put his honesty to so severe a trial, does he betray any insecurity as to his character and reputation amongst them? So far from this, that in arguing the general doctrine of resurrection from the dead, as the most effectual method of securing assent to it, he rests the main part of the argument upon their confidence in his fidelity as a witness. "But if there be no resurrection from the dead, then is Christ not risen. - - - - Yea, and we are found false witnesses of God, because we have testified of God, that he raised up Christ, whom he raised not up, if so be that the dead rise not." Where, we ask, would have been the mighty charm of this argument, if Paul's fidelity had been questioned; and how shall we account for the free and intrepid manner in which he advances it, if the miracles which he refers to, as wrought among them, had been nullities of his own invention?

128. For the truth of the gospel history, we can appeal to one strong and unbroken series of testimonies from the days of the apostles. But the great strength of the evidence lies in that effulgence of testimony, which enlightens this history at its commencement—in the number of its original witnesses—in the distinct and independent records which they left behind them, and in the undoubted faith they bore among the numerous societies which they instituted. The concurrence of the apostolic fathers, and their immediate successors, forms a very strong and a very satisfying argument; but let it be further remembered, that out of the materials which compose, if we may be allowed the expression, the original charter of our faith, we can select a stronger body of evidence than it is possible to form out of the whole mass of subsequent testimonies.

Prophecy.

129. Prophecy is another species of evidence which Christianity professes an abundant claim to, and which can be established on evidence altogether distinct from the testimony of its supporters. The prediction of what is future may not be delivered in terms so clear and intelligible as the history of what is past; and yet, in its actual fulfilment, it may leave no doubt on the mind of the enquirer that it was a prediction, and that the event in question was in the contemplation of him who uttered it. It may be easy to dispose of one isolated prophecy, by ascribing it to accident; but when we observe a number of these prophecies, delivered in different ages, and all bearing an application to the same events, or the same individual, it is difficult to resist the impression that they were actuated by a knowledge superior to human.

130. The obscurity of the prophetical language has been often complained of; but it is not so often attended to, that if the prophecy which fortels an event were as clear as the narrative which describes, it would in many cases annihilate the argument. Were the history of any individual foretold in terms as explicit as it is in the power of narrative to make them, it might be competent for any usurper to set himself forward, and in as far as it depended upon his own agency, he might realize that history. He has no more to do than to take his lesson from the prophecy before him; but could it be said that fulfilment like this carried in it the evidence of any thing divine or miraculous? If the prophecy of a Prince and a Saviour, in the Old Testament, were different from what they are, and delivered in the precise and intelligible terms of an actual history; then every accomplishment which could be brought about by the agency of those who understood the prophecy, and were anxious for its verification, is lost to the argument. It would be instantly said that the agents in the transaction took their clue from the prophecy before them. It is the way, in fact, in which infidels have attempted to evade the argument as it actually stands. In the New Testament, an event is sometimes said to happen that *it might be fulfilled*, what was spoken by some of the old prophets. If every event which enters into the gospel had been under the controul of agents merely human, and friends to Christianity; then we might have had reason to pronounce the whole history to be one continued process of artful and designed accommodation to the Old Testament prophecies. But the truth is, that many of the events pointed at in the Old Testament, so far from being brought about by the agency of Christians, were brought about in opposition to their most anxious wishes. Some of them were brought about by the agency of their most decided enemies; and some of them, such as the dissolution of the Jewish state, and the dispersion of its people amongst all countries, were quite beyond the controul of the apostles and their followers, and were effected by the intervention of a neutral party, which at the time took no interest in the question, and which was a stranger to the prophecy, though the unconscious instrument of its fulfilment.

131. Lord Bolingbroke has carried the objection so far, that he asserts Jesus Christ to have brought on his own death, by a series of wilful and preconcerted measures, merely to give the disciples who came after him the triumph of an appeal to the old prophecies. This is ridiculous enough; but it serves to shew with what facility an infidel might have evaded the whole argument, had these prophecies been free of all that obscurity which is now so loudly complained of.

132. The best form for the purposes of argument in which a prophecy can be delivered, is to be so obscure, as

to leave the event, or rather its main circumstances, unintelligible before the fulfilment, and so clear as to be intelligible after it. It is easy to conceive that this may be an attainable object; and it is saving much for the argument as it stands, that this happiest illustrations of the clearness on the one hand, and this obscurity on the other, are to be gathered from the actual prophecies of the Old Testament.

133. It is not, however, by this part of the argument, that we expect to reclaim the enemy of our religion from his infidelity; not that the examination would not satisfy him, but that the examination will not be given. What a violence it would be offering to all his antipathies, were we to land him, at the outset of our discussions, among the chapters of Daniel or Isaiah! He has too inveterate a contempt for the Bible. He nauseates the whole subject too strongly to be prevailed upon to accompany us to such an exercise. On such a subject as this, there is no contrast, no approximation betwixt us; and we leave him with the assertion, (an assertion which he has no title to pronounce upon, till after he has finished the very examination which we are most anxious to engage him in), that in the numerous prophecies of the Old Testament, there is such a multitude of allusions to the events of the New, as will give a strong impression to the mind of every enquirer, that the whole forms one magnificent series of communications betwixt the visible and the invisible world; a great plan over which the unseen God presides in wisdom, and which, beginning with the first ages of the world, is still receiving new developements from every great step in the history of the species.

134. It is impossible to give a complete exposition of this argument without an actual reference to the prophecies themselves; and this would lead us far beyond the limits of our article. But it can be conceived, that a prophecy, when first announced, may be so obscure, as to be unintelligible in many of its circumstances; and yet may so far explain itself by its accomplishment, as to carry along with it the most decisive evidence of its being a prophecy. And the argument may be so far strengthened by the number, and distance, and independence, of the different prophecies, all bearing an application to the same individual and the same history, as to leave no doubt on the mind of the observer, that the events in question were in the actual contemplation of those who uttered the prediction. If the terms of the prophecy were not comprehended, it at least takes off the suspicion of the event being brought about by the controul or agency of men who were interested in the accomplishment. If the prophecies of the Old Testament are just invested in such a degree of obscurity, as is enough to disguise many of the leading circumstances from those who lived before the fulfilment,—while they derive from the event an explanation satisfying to all who live after it, then, we say, the argument for the divinity of the whole is stronger, than if no such obscurity had existed. In the history of the New Testament, we see a natural and consistent account of the delusion respecting the Messiah, in which this obscurity had left the Jewish people—of the strong prejudices, even of the first disciples—of the manner in which these prejudices were dissipated, only by the accomplishment—and of their final conviction in the import of these prophecies being at last so strong, that it often forms their main argument for the divinity of that new religion which they were commissioned to publish to the world. Now, assuming, what we still persist in asserting, and ask to be tried upon, that an actual comparison of the prophecies in the Old Testament, with their alleged fulfilment in the New, will leave a conviction behind it, that there is a real correspondence betwixt them; we see, in the great events of the new dispensation brought about by the blind instrumentality of prejudice and opposition, far more unambiguous characters of the finger of God, than if every thing had happened with the full concurrence and anticipation of the different actors in this history.

135. There is another essential part of the argument, which is much strengthened by this obscurity. It is necessary to fix the date of the prophecies, or to establish, at least, that the time of their publication was antecedent to the events to which they refer. Now, had these prophecies been delivered in terms so explicit, as to force the concurrence of the whole Jewish nation, the argument for their antiquity, would not have come down in a form as satisfying, as that in which it is actually exhibited. The testimony of the Jews, to the date of their sacred writings, would have been refused as an interested testimony. Whereas, to evade the argument as it stands, we must admit a principle, which, in no question of ordinary criticism, would be suffered for a single moment to influence your understanding. We must conceive, that two parties, at the very time that they were influenced by the strongest mutual hostility, combined to support a fabrication; that they have not violated this combination; that the numerous writers on both sides of the question have not suffered the slightest hint of this mysterious compact to escape them; and that, though the Jews are galled incessantly by the triumphant tone of the Christian appeals to their own prophecies, they have never been tempted to let out a secret, which would have brought the argument of the Christians into disgrace, and shown the world, how falsehood and forgery mingled with their pretensions.

136. In the rivalry which, from the very commencement of our religion, has always obtained betwixt Jews and Christians, in the mutual animosities of Christian sects, in the vast multiplication of copies of the scriptures, in the distant and independent societies which were scattered over so many countries, we see the most satisfying pledge, both for the integrity of the sacred writings, and for the date which all parties agree in ascribing to them. We hear of the many securities which have been provided in the various forms of registrations, and duplicates, and depositories; but neither the wisdom, nor the interests of men, ever provided more effectual checks against forgery and corruption, than we have in the instance before us. And the argument, in particular, for the antecedence of the prophecies to the events in the New Testament, is so well established by the concurrence of the two rival parties, that we do not see, how it is in the power of additional testimony to strengthen it.

137. But neither is it true, that the prophecies are delivered in terms so obscure, as to require a painful examination, before we can obtain a full perception of the argument. Those prophecies which relate to the fate of particular cities, such as Nineveh, and Tyre, and Babylon; those which relate to the issue of particular wars, in which the kings of Israel and Judah were engaged; and some of those which relate to the future history of the adjoining countries, are not so much veiled by symbolical language, as to elude the understanding, even of the most negligent observers. It is true, that in these instances, both the prophecy and the fulfilment appear to us in the light of a distant antiquity. They have accomplished their end. They kept alive the faith and worship of successive generations. They multiplied the evidences of the true

religion, and account for a phenomenon in ancient history that is otherwise inexplicable, the existence and preservation of one solitary monument of pure theism in the midst of a corrupt and idolatrous world.

138. But to descend a little further. We gather from the state of opinions at the time of our Saviour so many testimonies to the clearness of the old prophecies. The time and the place of our Saviour's appearance in the world, and the triumphant progress, if not the nature of his kingdom, were perfectly understood by the priests and chief men of Judea. We have it from the testimony of profane authors, that there was, at that time, a general expectation of a prince and a prophet all over the East. The destruction of Jerusalem was another example of the fulfilment of a clear prophecy; and this, added to other predictions uttered by our Saviour, and which received their accomplishment in the first generation of the Christian church, would have its use in sustaining the faith of the disciples amidst the perplexities of that anxious and distressing period.

139. We can even come down to the present day, and point to the accomplishment of clear prophecies in the actual history of the world. The present state of Egypt, and the present state of the Jews, are the examples which we fix upon. The one is an actual fulfilment of a clear prophecy; the other is also an actual fulfilment, and forms in itself the likeliest preparation for another accomplishment that is yet to come. Nor do we conceive, that these clear and literal fulfilments exhaust the whole of the argument from prophecy. They only form one part of the argument, but a part so obvious and irresistible, as should invite every lover of truth to the examination of the remainder. They should secure such a degree of respect for the subject, as to engage the attention, and awaken even in the mind of the most rapid and superficial observer, a suspicion that there may be something in it. They should soften that contempt which repels so many from investigating the argument at all, or at all events, they render that contempt inexcusable.

140. The whole history of the Jews is calculated to allure the curiosity, and had it not been leagued with the defence and illustration of our faith, would have drawn the attention of many a philosopher, as the most singular exhibition of human nature that ever was recorded in the annals of the world. The most satisfying cause of this phenomenon is to be looked for in the history, which describes its origin and progress; and by denying the truth of that history, you abandon the only explanation which can be given of this wonderful people. It is quite in vain to talk of the immutability of Eastern habits, as exemplified in the nations of Asia. What other people ever survived the same annihilating processes? We do not talk of conquest, where the whole amount of the effect is in general a change of dynasty or of government; but where the language, the habits, the denomination, and above all, the geographical position, still remain to keep up the identity of the people. But in the history of the Jews, we see a strong indestructible principle, which maintained them in a separate form of existence amid changes that no other nation ever survived. We confine ourselves to the overthrow of their nation in the first century of our epoch, and appeal to the disinterested testimonies of Tacitus and Josephus, if ever the cruelty of war devised a process of more terrible energy for the utter extirpation of a name, and a remembrance from the world. They have been dispersed among all countries. They have no common tie of locality or government to keep them together. All the ordinary principles of assimilation, which make law, and religion, and manners, so much a matter of geography, are in their instance suspended. Even the smallest particles of this broken mass have resisted an affinity of almost universal operation, and remain undiluted by the strong and overwhelming admixture of foreign ingredients. And in exception to every thing which history has recorded of the revolutions of the species, we see in this wonderful race a vigorous principle of identity which has remained in undiminished force for nearly two thousand years, and still pervades every shred and fragment of their widely scattered population. Now, if the infidel insists upon it, we shall not rest on this as an argument. We can afford to give it up; for in the abundance of our resources, we feel independent of it. We shall say that it is enough, if it can reclaim him from his levity, and compel his attention to the other evidences which we have to offer him. All we ask of him is to allow, that the undeniable singularity which is before his eyes, gives him a sanction at least, to examine the other singularities which we make pretension to. If he goes back to the past history of the Jews, he will see in their wars the same unexampled preservation of their name and their nation. He will see them surviving the process of an actual transportation into another country. In short, he will see them to be unlike all other people in what observation offers, and authentic history records of them; and the only concession that we demand of him from all this, is, that their pretension to be unlike other people in their extraordinary revelations from heaven is at least possible, and deserves to be enquired into.

141. It may not be out of place to expose a species of injustice, which has often been done to the Christian argument. The defence of Christianity consists of several distinct arguments, which have sometimes been multiplied beyond what is necessary, and even sometimes beyond what is tenable. In addition to the main evidence which lies in the testimony given to the miracles of the gospel, there is the evidence of prophecy; there is the evidence of collateral testimony; there is the internal evidence. The argument under each of these heads, is often made to undergo a farther subdivision; and it is not to be wondered at, that, in the multitude of observations, the defence of Christianity may often be made to rest upon ground, which, to say the least of it, is precarious or vulnerable. Now the injustice which we complain of is, that when the friends of our religion are dislodged from some feeble outwork, raised by an unskilful officer in the cause, its enemies raise the cry of a decisive victory. But, for our own part, we could see her driven from all her defences, and surrender them without a sigh, so long as the phalanx of her historical evidence remains impenetrable. Behind this unscaled barrier, we could entrench ourselves, and eye the light skirmishing before us with no other sentiment than of regret, that our friends should, by the eagerness of their misplaced zeal, have given our enemy the appearance of a triumph.

142. We offer no opinion as to the two-fold interpretation of prophecy; but though it were refuted by argument, and disgraced by ridicule, all that portion of evidence which lies in the numerous examples of literal and unambiguous fulfilment remains unaffected by it. Many there are, who deny the inspiration of the Song of Solomon. But in what possible way does this affect the records of the evangelical history? Just as much as it affects the Lives of Plutarch, or the Annals of Tacitus. There are a thousand subjects in which infidels may idly push the triumph, and Christians be as idly galled by the severity, or even the truth of their observations. We point to the historical evidence for the New

Testament, and ask them to dispose of it. It is there, that we call them to the onset; for there lies the main strength of the Christian argument. It is true, that in the evidence of prophecy, we see a rising barrier, which, in the progress of centuries, may receive from time to time a new accumulation to the materials which form it. In this way, the evidence of prophecy may come in time to surpass the evidence of miracles. The restoration of the Jews will be the fulfilment of a clear prophecy, and form a proud and animating period in the history of our religion, "the fall of them the riches of the world, and the diminishing of them the riches of the Gentiles, how much more their fulness?"

Geological objections considered.

143. The late speculations in geology form another example of a distant and unconnected circumstance, being suffered to cast an unmerited disgrace over the whole of the argument. They give a higher antiquity to the world, than most of those who read the Bible had any conception of. Admit this antiquity, and in what possible way does it touch upon the historical evidence for the New Testament? The credibility of the gospel miracles stands upon its own appropriate foundation, the recorded testimony of numerous and unexceptionable witnesses. The only way in which we can overthrow that credibility is by attacking the testimony, or disproving the authenticity of the record. Every other science is tried upon its own peculiar evidences; and all we contend for is, that the same justice be done to theology. When a mathematician offers to apply his reasoning to the phenomena of mind, the votaries of moral science resent it as an invasion, and make their appeal to the evidence of consciousness. When an amateur of botany, upon some vague analogies, offers his confident affirmations as to the structure and parts of the human body, there would be an instantaneous appeal to the knife and demonstrations of the anatomist. Should a mineralogist, upon the exhibition of an ingenious or well-supported theory, pronounce upon the history of our Saviour and his miracles, we would call it another example of an arbitrary and unphilosophical extension of principles beyond the field of their legitimate application. We would appeal to the kind and the quantity of testimony upon which that history is supported. We would suffer ourselves to be delighted by the brilliancy, or even convinced by the evidence of his speculations, but we would feel that the history of these facts, which form the groundwork of our faith, is as little affected by them, as the history of any storm, or battle, or warrior, which has come down to us in the most genuine and approved records of past ages.

144. But whatever be the external evidence of testimony, or however strong may be its visible characters of truth and honesty, is not the falsehood or the contradiction which we may detect in the subject of that testimony sufficient to discredit it? Had we been original spectators of our Saviour's miracles, we must have had as strong a conviction of their reality, as it is in the power of testimony to give us. Had we been the eye-witnesses of his character and history, and caught from actual observation the impression of his worth, the internal proofs, that no jugglery or falsehood could have been intended, would have been certainly as strong as the internal proofs which are now exhibited to us, and which consist in the simplicity of the narrative, and that tone of perfect honesty which pervades in a manner so distinct and intelligible every composition of the apostles. Yet, with all these advantages, if Jesus Christ had asserted as a truth, what we confidently know to be a falsehood; had he, for example, upon the strength of his prophetical endowments, pronounced upon the secret of a person's age, and told us that he was thirty, when we knew him to be forty, would not this have made us stumble at all his pretensions, and, in spite of every other argument and appearance, would we not have withdrawn our confidence from him as a teacher from God? This we allow would have been a most serious dilemma. It would have been that state of neutrality which admits of nothing positive or satisfying on either side of the question; or rather, what is still more distressing, which gave me the most positive and satisfactory appearances on both sides. We could not abandon the truth of the miracles, because we saw them. Could we give them up, we should determine on a positive rejection, and our minds would find repose in absolute infidelity. But as the case stands, it is scepticism. There is nothing like it in any other department of inquiry. We can appeal to no actual example; but a student of natural science may be made to understand the puzzle. When he asks him, how he would act, if the experiments, which he conducts under the most perfect sameness of circumstances, were to land him in opposite results? He would vary and repeat his experiments. He would try to detect the inconsistency, and would rejoice, if he at last found, that the difficulty lay in the errors of his own observation, and not in the inexplicable nature of the subject. All this he would do in anxious and repeated endeavours, before he inferred that nature persevered in no law, and that that constancy, which is the foundation of all science, was perpetually broke in upon by the most capricious and unlooked for appearances, before he would abandon himself to scepticism, and pronounce philosophy to be an impossible attainment.

145. It is our part to imitate this example. If Jesus Christ has, on the one hand, performed miracles, and sustained in the whole tenour of his history the character of a prophet, and, on the other hand, asserted to be true, what we undeniably know to be a falsehood, this is a dilemma which we are called upon to resolve by every principle, that can urge the human mind in the pursuit of liberal inquiry. It is not enough to say, that the phenomena in question do not fall within the dominion of philosophy; and we therefore leave them as a fair exercise and amusement to commentators. The mathematician may say, and has said the same thing of the moralist; yet there are moralists in the world, who will prosecute their speculations in spite of him; and what is more, there are men who take a wider survey than either, who rise above these professional prejudices, and will allow that, in each department of inquiry, the subjects which offer are entitled to a candid and respectful consideration. The naturalist may pronounce the same rapid judgment upon the difficulties of the theologian; yet there ever will be theologians who feel a peculiar interest in their subject; and we trust that there ever will be men, with a higher grasp of mind than either the mere theologian, or the mere naturalist, who are ready to acknowledge the claims of truth in every quarter,—who are superior to that narrow contempt, which has made such an unhappy and malignant separation among the different orders of scientific men,—who will examine the evidences of the gospel history, and, if they are found to be sufficient, will view the miracles of our Saviour with the same liberal and philosophic curiosity with which they would contemplate any grand phenomenon in the moral history of the species. If there really appears, on the face of this investigation, to be such a difficulty as the one in question, a philosopher of the order we are now describing will make many an anxious effort to extricate himself; he will not soon acquiesce in a scepticism, of

which there is no other example in the wide field of human speculation; he will either make out the insufficiency of the historical evidence, or prove that the falsehood ascribed to Jesus Christ has no existence. He will try to dispose of one of the terms of the alleged contradiction, before he can prevail upon himself to admit both, and deliver his mind to a state of uncertainty most painful to those who respect truth in all her departments.

146. We offer the above observations, not so much for the purpose of doing away a difficulty which we conscientiously believe to have no existence, as for the purpose of exposing the rapid, careless, and unphilosophical procedure of some enemies to the Christian argument. They, in the first instance, take up the rapid assumption, that Jesus Christ has, either through himself, or his immediate disciples, made an assertion as to the antiquity of the globe, which, upon the faith of their geological speculations, they know to be a falsehood. After having fastened this stain upon the subject of the testimony, they, by one summary act of the understanding, lay aside all the external evidence for the miracles and general character of our Saviour. They will not wait to be told, that this evidence is a distinct subject of examination; and that, if actually attended to, it will be found much stronger than the evidence of any other fact or history which has come down to us in the written memorials of past ages. If this evidence is to be rejected, it must be rejected on its own proper grounds; but if all positive testimony, and all sound reasoning upon human affairs, go to establish it, then the existence of such proof is a phenomenon which remains to be accounted for, and must ever stand in the way of positive infidelity. Until we dispose of it, we can carry our opposition to the claims of our religion no farther than to the length of an ambiguous and mid-way scepticism. By adopting a decisive infidelity, we reject a testimony, which, of all others, has come down to us in the most perfect and unsuspicious form. We lock up a source of evidence, which is often repaired to in other questions of science and history. We cut off the authority of principles, which, if once exploded, will not terminate in the solitary mischief of darkening and destroying our theology, but will shed a baleful uncertainty over many of the most interesting speculations on which the human mind can expatiate.

147. Even admitting, then, this single objection in the subject of our Saviour's testimony, the whole length to which we can legitimately carry the objection is scepticism, or that dilemma of the mind into which it is thrown by two contradictory appearances. This is the unavoidable result of admitting both terms in the alleged contradiction. Upon the strength of all the reasoning which has hitherto occupied this article, we challenge the infidel to dispose of the one term which lies in the strength of the historical evidence. But we undertake to dispose of the other which lies in the alleged falsehood of our Saviour's testimony. We will not try to make our escape, by denying the truth of the geological speculation. We are not afraid to own that we are impressed by its evidence, and feel our imagination regaled by its brilliancy. We will not try to do away the supposed falsehood, by asserting what has been called the Mosaical antiquity of the world; but we deny that our Saviour ever asserted this antiquity. It is true that he gives his distinct testimony to the divine legation of Moses; but does Moses ever say, that when God created the heavens and the earth, he did more at the time alluded to than transform them out of previously existing materials? Or does he ever say, that there was not an interval of many ages betwixt the first act of creation, described in the first verse of the book of Genesis, and said to have been performed at the *beginning;* and those more detailed operations, the account of which commences at the second verse, and which are described to us under the allegory of days?—Or does he ever bring forward any literal interpretation of this history which brings him into the slightest contact with the doctrines of geology? Or, finally, does he ever make us to understand, that the genealogies of man went any farther than to fix the antiquity of the species, and, of consequence, that they left the antiquity of the globe a free subject for the speculations of philosophers? The historical evidence remains in all the obstinacy of experimental and well-attested facts; and as there are so many ways of expunging the other term in the alleged contradiction, we appeal to every enlightened reader, if it is at all candid or philosophical to suffer it to stand?

Internal evidence considered.

148. There is another species of evidence for Christianity which we have not yet noticed. What is commonly called the *internal evidence*, or those proofs that Christianity is a dispensation from heaven, founded upon the nature of its doctrines, and the character of the dispensation itself. The term "internal evidence" may be made indeed to take up more than this. We may take up the New Testament as a human composition, and without any reference to its subsequent history, or to the direct and external testimonies by which it is supported. We may collect from the performance itself such marks of truth and honesty, as entitle us to conclude, that the human agents employed in the construction of this book were men of veracity and principle. This argument has already been resorted to, and a very substantial argument it is. It is of frequent application in questions of general criticism; and upon its authority alone many of the writers of past times have been admitted into credit, and many have been condemned as unworthy of it. The numerous and correct allusions to the customs and institutions, and other statistics of the age in which the pieces of the New Testament profess to have been written, give evidence of their antiquity. The artless and undesigned way in which these allusions are interwoven with the whole history, impresses upon us the perfect simplicity of the authors, and the total absence of every wish or intention to palm an imposture upon the world. And there is such a thing too as a general air of authenticity, which, however difficult to resolve into particulars, gives a very close and powerful impression of truth to the narrative. There is nothing fanciful in this species of internal evidence. It carries in it all the certainty of experience, and experience too upon a familiar and well known subject,—the characters of honesty in the written testimony of our fellow men. We are often called upon in private and every-day life to exercise our judgment upon the spoken testimony of others, and we both feel and understand the powerful evidence which lies in the tone, the manner, the circumstantiality, the number, the agreement of the witnesses, and the consistency of all the particulars with what we already know from other sources of information. Now it is undeniable, that all those marks which give evidence and credibility to spoken testimony, may also exist to a very impressive degree in written testimony; and the argument founded upon them, so far from being fanciful or illegitimate, has the sanction of a principle which no philosopher will refuse; the expe-

rience of the human mind on a subject on which it is much exercised, and which lies completely within the range of its observation.

149. We cannot say so much, however, for the other species of internal evidence, that which is founded upon the reasonableness of the doctrines, or the agreement which is conceived to subsist betwixt the nature of the Christian religion and the character of the Supreme Being. We have experience of man, but we have no experience of God. We can reason upon the procedure of man in given circumstances, because this is an accessible subject, and comes under the cognizance of observation; but we cannot reason on the procedure of the Almighty in given circumstances. This is an inaccessible subject, and comes not within the limits of direct and personal observation. The one, like the scale, and compass, and measurements of Sir Isaac Newton, will lead you on safe and firm footing to the true economy of the heavens; the other, like the ether and whirlpools, and unfounded imaginations of Des Cartes, will not only lead you to misconceive that economy, but to maintain a stubborn opposition to the only competent evidence that can be offered upon the subject.

150. The writer of the present article feels, that in thus disclaiming all support from what is commonly understood by the internal evidence, he does not follow the general example of those who have written on the Deistical controversy. Take up Leland's performance, and it will be found, that one half of his discussion is expended upon the reasonableness of the doctrines, and in asserting the validity of the argument which is founded upon that reasonableness. It would save a vast deal of controversy, if it could be proved that all this is superfluous and uncalled for; that upon the authority of the proofs already insisted on, the New Testament must be received as a revelation from heaven; and that, instead of sitting in judgment over it, nothing remains on our part, but an act of unreserved submission to all the doctrine and information which it offers to us. It is conceived, that in this way the general argument might be made to assume a more powerful and impressive aspect; and it is hoped, that the reader will not look upon the article as prolonged to an unnecessary length, if, by unfolding the speculation, the defence of Christianity can be more accommodated to the spirit and philosophy of the times.

151. Since the spirit of Lord Bacon's philosophy began to be rightly understood, the science of external nature has advanced with a rapidity unexampled in the history of all former ages. The great axiom of his philosophy is so simple in its nature, and so undeniable in its evidence, that it is astonishing how philosophers were so late in acknowledging it, or in being directed by its authority. It is more than two thousand years since the phenomena of external nature were objects of liberal curiosity to speculative and intelligent men. Yet two centuries have scarcely elapsed since the true path of investigation has been rightly pursued, and steadily persevered in. Since the evidence of experience has been received as paramount to every other evidence, or, in other words, since philosophers have agreed that the only way to learn the magnitude of an object is to measure it, the only way to learn its tangible properties is to touch it, and the only way to learn its visible properties is to look at it.

152. Nothing can be more safe or more infallible than the procedure of the inductive philosophy as applied to the phenomena of external nature. It is the eye, or the ear-witness of every thing which it records. It is at liberty to classify appearances, but then in the work of classifying, it must be directed only by observation. It may groupe phenomena according to their resemblances. It may express these resemblances in words, and announce them to the world in the form of general laws. Yet such is the hardihood of the inductive philosophy, that though a single well-attested fact should overturn a whole system, that fact must be admitted. A single experiment is often made to cut short the finest process of generalization, however painful and humiliating the sacrifices, and though a theory, the most simple and magnificent that ever charmed the eye of an enthusiast, was on the eve of emerging from it.

153. In submitting, then, to the rules of the inductive philosophy, we do not deny that certain sacrifices must be made, and some of the most urgent propensities of the mind, put under severe restraint and regulation. The human mind feels restless and dissatisfied under the anxieties of ignorance. It longs for the repose of conviction; and to gain this repose, it will often rather precipitate its conclusions, than wait for the tardy lights of observation and experiment. There is such a thing, too, as the love of symplicity and system—a prejudice of the understanding, which disposes it to include all the phenomena of nature under a few sweeping generalities—an indolence, which loves to repose on the beauties of a theory, rather than encounter the fatiguing detail of its evidence—a painful reluctance to the admission of facts, which, however true, break in upon the majestic simplicity that we would fain ascribe to the laws and operations of the universe.

154. Now, it is the glory of Lord Bacon's philosophy, to have achieved a victory over all these delusions—to have disciplined the minds of its votaries into an entire submission to evidence—to have trained them up in a kind of steady coldness to all the splendour and magnificence of theory, and taught them to follow, with an unfaultering step, wherever the sure though humbler path of experiment may lead them.

155. To justify the cautious procedure of the inductive philosophy, nothing more is necessary than to take a view of the actual powers and circumstances of humanity; of the entire ignorance of man, when he comes into the world, and of the steps by which that ignorance is enlightened; of the numerous errors into which he is misled, the moment he ceases to observe, and begins to presume or to excogitate; of the actual history of science; its miserable progress, so long as categories and principles retained their ascendency in the schools; and the splendour and rapidity of its triumphs, so soon as man understood, that he was nothing more than the disciple of Nature, and must take his lesson as Nature offers it to him.

156. What is true of the science of external nature holds equally true of the science and phenomena of mind. On this subject, too, the presumptuous ambition of man carried him far from the sober path of experimental inquiry. He conceived that his business was not to observe, but to speculate; to construct systems rather than consult his own experience, and the experience of others; to collect the materials of his theory, not from the history of observed facts, but from a set of assumed and excogitated principles. Now the same observations apply to this department of inquiry. We must admit to be true not what we presume, but what we find to be so. We must restrain the enterprises of fancy. A law of the human mind must be only a series of well authenticated facts, reduced to one general description, or grouped together under some general points of resemblance. The business of the moral as well as of the

natural philosopher is not to assert what he excogitates, but to record what he observes; not to amuse himself with the speculations of fancy, but to describe phenomena as he sees or as he feels them. This is the business of the moral as well as of the natural enquirer. We must extend the application of Lord Bacon's principles to moral and metaphysical subjects. It was long before this application was recognized, or acted upon by philosophers. Many of the continental speculations are still infected with the presumptuous, *a priori* spirit of the old schools; though the writings of Reid and Stewart have contributed much to chase away this spirit from the metaphysics of our own country, and to bring the science of mind, as well as matter, under the entire dominion of the inductive philosophy.

157. These general observations we conceive to be a most direct and applicable introduction to that part of the subject which is before us. In discussing the evidence of Christianity, all that we ask of our reader is to bring along with him the same sober and inductive spirit, that is now deemed so necessary in the prosecution of the other sciences; to abandon every system of theology, that is not supported by evidence, however much it may gratify his taste, or regulate his imagination, and to admit any system of theology, that is supported by evidence, however repugnant to his feelings or his prejudices; to make conviction, in fact, paramount to inclination, or to fancy; and to maintain, through the whole process of the investigation, that strength and intrepidity of character, which will follow wherever the light of argument may conduct, though it should land him in conclusions the most nauseous and unpalatable.

158. We have no time to enter into causes; but the fact is undeniable. Many philosophers of the present day are disposed to nauseate every thing connected with theology. They associate something low and ignoble with the prosecution of it. They regard it, as not a fit subject for liberal enquiry. They turn away from it with disgust, as one of the humblest departments of literary exertion. We do not say that they reject its evidences, but they evade the investigation of them. They feel no conviction; not because they have established the fallacy of a single argument, but because they entertain a general dislike at the subject, and will not attend to it. They love to expatiate in the more kindred fields of science or elegant literature; and while the most respectful caution, and humility, and steadiness, are seen to preside over every department of moral and physical investigation, theology is the only subject that is suffered to remain the victim of prejudice, and of a contempt the most unjust, and the most unphilosophical.

159. We do not speak of this feeling as an impiety; we speak of it as an offence against the principles of just speculation. We do not speak of it as it allures the heart from the influence of religion; we speak of it as it allures the understanding from the influence of evidence and truth. In a word, we are not preaching against it; we reason against it. We contend that it is a transgression against the rules of the inductive philosophy. All that we want is, the application of Lord Bacon's principles to the investigation before us; and as the influence of prejudice and disgust is banished from every other department of enquiry, we conceive it fair that it should be banished from theology also, and that our subject should have the common advantage of a hearing,—where no partiality of the heart or fancy is admitted, and no other influence acknowledged, than the influence of evidence over the conviction of the understanding.

160. Let us therefore evince the success and felicity with which Lord Bacon's principles may be applied to the investigation before us.

161. According to Bacon, man is ignorant of every thing antecedent to observation, and there is not a single department of enquiry in which he does not err the moment that he abandons it. It is true, that the greater part of every individual's knowledge is derived immediately from testimony; but it is only testimony that brings home to his conviction the observation of others. Still it is observation which lies at the bottom of his knowledge. Still it is man taking his lesson from the actual condition of the thing which he contemplates; a condition that is altogether independent of his will, and which no speculation of his own can modify or destroy. There is an obstinacy in the processes of nature which he cannot controul. He must follow it. The construction of a system should not be a creative, but an imitative process, which admits nothing but what evidence assures us to be true, and is founded only on the lessons of experience. It is not by the exercise of a sublime and speculative ingenuity that man arrives at truth. It is by letting himself down to the drudgery of observation. It is by descending to the sober work of seeing, and feeling, and experimenting. Wherever, in short, he has not had the benefit of his own observation, or the observation of others brought home to his conviction by creditable testimony, there he is ignorant.

162. This is found to hold true, even in those sciences, where the objects of enquiry are the most familiar and the most accessible. Before the right method of philosophising was acted upon, how grossly did philosophers misinterpret the phenomena of external nature! When a steady perseverence in the path of observation could have led them to infallible certainty, how misled in their conception of every thing around them, when, instead of making use of their senses, they delivered themselves up to the exercises of a solitary abstraction, and thought to explain every thing by the fantastic play of unmeaning terms, and imaginary principles! And, when at last set on the right path of discovery, how totally different were the results of actual observation, from those systems which antiquity had rendered venerable, and the authority of great names had recommended to the acquiescence of many centuries! This proves, that, even in the most familiar subjects, man knows every thing by observation, and is ignorant of every thing without it; and that he cannot advance a single footstep in the acquirement of truth, till he bid adieu to the delusions of theory, and sternly refuse indulgence to its fondest anticipations.

163. Thus, there is both a humility and a hardihood in the philosophical temper. They are the same in principle, though different in display. The first is founded on a sense of ignorance, and disposes the mind of the philosopher to pay the most respectful attention to every thing that is offered in the shape of evidence. The second consists in a determined purpose to reject and to sacrifice every thing that offers to oppose the influence of evidence, or to set itself up against its legitimate and well established conclusions. In the ethereal whirlpools of Des Cartes, we see a transgression against the humility of the philosophical character. It is the presumption of knowledge on a subject, where the total want of observation should have confined him to the modesty of ignorance. In the Newtonian system of the world, we see both humility and hardihood. Sir Isaac commences his investigation with all the modesty of a respectful enquirer. His is the docility of a scholar, who is sensible

that he has all to learn. He takes his lesson as experience offers it to him, and yields a passive obedience to the authority of this great school-master. It is in his obstinate adherence to the truth which his master has given him, that the hardihood of the philosophical character begins to appear. We see him announce, with entire confidence, both the fact and its legitimate consequences. We see him not deterred by the singularity of his conclusions, and quite unmindful of that host of antipathies which the reigning taste and philosophy of the times mustered up to oppose him. We see him resisting the influence of every authority, but the authority of experience. We see that the beauty of the old system had no power to charm him from that process of investigation by which he destroyed it. We see him sitting upon its merits with the severity of a judge, unmoved by all those graces of simplicity and magnificence, which the sublime genius of its inventor had thrown around it.

164. We look upon these two constituents of the philosophical temper, as forming the best preparation for finally terminating in the decided Christian. In appretiating the pretensions of Christianity, there is a call both upon the humility and the hardihood of every enquirer; the humility which feels its own ignorance, and submits without reserve to whatever comes before it in the shape of authentic and well-established evidence; and the hardihood, which sacrifices every taste and every prejudice at the shrine of conviction, which defies the scorn of a pretended philosophy, which is not ashamed of a profession that some conceive to be degraded by the homage of the superstitious vulgar, which can bring down its mind to the homeliness of the gospel, and renounce without a sigh all that is elegant, and splendid, and fascinating in the speculations of moralists. In attending to the complexion of the Christian argument, we are widely mistaken, if it is not precisely that kind of argument, which will be most readily admitted by those whose minds have been trained to the soundest habits of philosophical investigation; and if that spirit of cautious and sober-minded enquiry to which modern science stands indebted for all her triumphs, is not the very identical spirit which leads us to "cast down all our lofty imaginations, and to bring every thought into the captivity of the obedience of Christ."

165. On entering into any department of enquiry, the best preparation is that docility of mind which is founded on a sense of our total ignorance of the subject; and nothing is looked upon as more unphilosophical than the temerity of that *a priori* spirit, which disposes many to presume before they investigate. But if we admit the total ignorance of man antecedent to observation, even in those sciences where the objects of enquiry are the nearest and the most familiar, we will be more ready to admit his total ignorance of those subjects which are more remote and more inaccessible. If caution and modesty be esteemed so philosophical, even when employed in that little field of investigation which comes within the range of our senses; why should they not be esteemed philosophical when employed on a subject so vast, so awful, so remote from direct and personal observation, as the government of God? There can be nothing so completely above us, and beyond us, as the plans of the Infinite Mind, which extend to all time, and embrace all worlds. There is no subject to which the cautious and humble spirit of Lord Bacon's philosophy is more applicable; nor can we conceive a more glaring rebellion against the authority of his maxims, than for the beings of a day to sit in judgment upon the Eternal, and apply their paltry experience to the counsels of his high and unfathomable wisdom. We do not speak of it as impious; we speak of it as unphilosophical. We are not bringing the decrees of the orthodox to bear against it; we are bringing the principles of our modern and enlightened schools. We are applying the very same principles to a system of theism, that we would do to a system of geology. Both may regale the fancy with the grandeur of their contemplations; both may receive embellishment from the genius and imagination of their inventors; both may carry us along with the powers of a captivating eloquence. But all this is not enough to satisfy the severe and scrupulous spirit of the modern philosophy. Give us facts. Give us appearances. Show us how, from the experience of a life or a century, you can draw a legitimate conclusion so boundless in its extent, and by which you propose to fix down both the processes of a remote antiquity, and the endless progressions either of nature or of providence in future ages. Are there any historical documents? Any memorials of the experience of past times? On a question of such magnitude we would esteem the recorded observations of some remote ages to be peculiarly valuable, and worth all the ingenuity and eloquence, which a philosopher could bestow on the limited experience of one or two generations. A process of geology may take millions of years before it reaches its accomplishment. It is impossible, that we can collect the law or the character of this process from the experience of a single century, which does not furnish us one single step in this vast and immeasureable progression. We look as far as we can into a distant antiquity, and take hold with avidity of any authentic document, by which we can ascertain a single fact to guide and to enlighten us in this interesting speculation. The same caution is necessary in the subject before us. The administration of the Supreme Being is coeval with the first purposes of his uncreated mind, and it points to eternity. The life of man is but a point in that progress, to which we see no end, and can assign no beginning. We are not able to collect the law or the character of this administration from an experience so momentary. We therefore cast an eye on the history of past times. We examine every document which comes before us. We compare all the moral phenomena, which can be collected from the narrative of antiquity. We seize with avidity every record of the manifestation of Providence, every fact which can enlighten the ways of God to man; and we would esteem it a deviation from the right spirit and temper of philosophical investigation, were we to suffer the crude or fanciful speculations of our own limited experience to take a precedency over the authentic information of history.

166. But this is not all. Our experience is not only limited in point of time; it is also limited in point of extent. To assign the character of the divine administration from the little that offers itself to the notice of our own personal experience, would be far more absurd than to infer the history and character of the kingdom from the history and character of our own families. Vain is the attempt to convey in language what the most powerful imagination sinks under; how small the globe, and all which it inherits, is in the immensity of creation! How humble a corner in the immeasurable fields of nature and of providence! If the whole visible creation were to be swept away, we think of the dark and awful solitude which it would leave behind it in the unpeopled regions of space. But to a mind that could take in the whole, and throw a wide survey over the innumerable worlds which roll beyond the ken of the human eye, there would be no blank, and the universe of

God would appear a scene as goodly and majestic as ever. Now it is the administration of this God that we sit in judgment upon; the counsels of Him, whose wisdom and energy are of a kind so inexplicable; whom no magnitude can overpower, whom no littleness can escape, whom no variety can bewilder; who gives vegetation to every blade of grass, and moves every particle of blood which circulates through the veins of the meanest animal; and all this by the same omnipotent arm that is abroad upon the universe, and presides in high authority over the destiny of all worlds.

167. It is impossible not to mingle the moral impressions of piety with such a contemplation. But suppose these impressions to be excluded, that the whole may be reduced to a matter of abstract and unfeeling intelligence. The question under consideration is, How far the experience of man can lead him to any certain conclusions, as to the character of the divine administration? If it does lead him to some certain conclusions, then, in the spirit of the Baconian philosophy, he will apply these conclusions to the information derived from other sources, and they will of course affect, or destroy, or confirm the credibility of that information. If, on the other hand, it appears that experience gives no light, no direction on the subject, then, in the very same spirit, he will submit his mind as a blank surface to all the positive information which comes to it from any other quarter. We take our lesson as it comes to us, provided we are satisfied beforehand, that it comes from a source which is authentic. We set up no presumptions of our own against the authority of the unquestionable evidence that we have met with, and reject all the suggestions which our defective experience can furnish, as the follies of a rash and fanciful speculation.

168. Now, let it be observed, that the great strength of the Christian argument lies in the historical evidence for the truth of the gospel narrative. In discussing the light of this evidence, we walk by the light of experience. We assign the degree of weight that is due to the testimony of the first Christians upon the observed principles of human nature. We do not step beyond the cautious procedure of Lord Bacon's philosophy. We keep within the safe and certain limits of experimental truth. We believe the testimony of the apostles, because, from what we know of the human character, it is impossible that men in their circumstances could have persevered as they did in the assertion of a falsehood; it is impossible that they could have imposed this falsehood upon such a multitude of followers; it is impossible that they could have escaped detection, surrounded as they were by a host of enemies, so eager and so determined in their resentments. On this kind of argument we are quite at home. There is no theory, no assumption. We feel every inch of the ground we are treading upon. The degree of credit that should be annexed to the testimony of the apostles is altogether a question of experience. Every principle which we apply towards the decision of this question, is founded upon materials which lie before us, and are every day within the reach of observation. Our belief in the testimony of the apostles is founded upon our experience of human nature and human affairs. In the whole process of the inquiry, we never wander from that sure, though humble path, which has been pointed out to us by the great master of philosophising. We never cast off the authority of those maxims, which have been found in every other department of knowledge to be sound and infallible. We never suffer assumption to take the precedency of observation, or abandon that safe and certain mode of investigation, which is the only one suited to the real mediocrity of our powers.

169. It appears to us, that the disciples of the infidel philosophy have reversed this process. They take a loftier flight. You seldom find them upon the ground of the historical evidence. It is not, in general, upon the weight, or the nature of human testimony, that they venture to pronounce on the credibility of the Christian revelation. It is on the character of that revelation itself. It is on what they conceive to be the absurdity of its doctrines. It is because they see something in the nature or dispensation of Christianity, which they think disparaging to the attributes of God, and not agreeable to that line of proceeding which the Almighty should observe in the government of his creatures. Rousseau expresses his astonishment at the strength of the historical testimony; so strong, that the inventor of the narrative appeared to him to be more miraculous than the hero. But the absurdities of this said revelation are sufficient in his mind to bear down the whole weight of its direct and external evidences. There was something in the doctrines of the New Testament repulsive to the taste and the imagination, and perhaps even to the convictions of this interesting enthusiast. He could not reconcile them with his pre-established conceptions of the divine character and mode of operation. To submit to these doctrines, he behoved to surrender that theism, which the powers of his ardent mind had wrought up into a most beautiful and delicious speculation. Such a sacrifice was not to be made. It was too painful. It would have taken away from him, what every mind of genius and sensibility esteems to be the highest of all luxuries. It would destroy a system, which had all that is fair and magnificent to recommend it, and mar the gracefulness of that fine intellectual picture, on which this wonderful man had bestowed all the embellishments of feeling, and fancy, and eloquence.

170. In as far, then, as we can judge of the conduct of man in given circumstances, we would pass a favourable sentence upon the testimony of the apostles. But, says the Deist, I judge of the conduct of God; and what the apostles tell me of him is so opposite to that judgment, that I discredit their testimony. The question at issue betwixt us is, shall we admit the testimony of the apostles, upon the application of principles founded on observation, and as certain as is our experience of human affairs? Or shall we reject that testimony upon the application of principles that are altogether beyond the range of observation, and as doubtful and imperfect in their nature, as is our experience of the counsels of Heaven? In the first argument there is no assumption. We are competent to judge of the behaviour of man in given circumstances. This is a subject completely accessible to observation. The second argument is founded upon assumption entirely. We are not competent to judge of the conduct of the Almighty in given circumstances. Here we are precluded, by the nature of the subject, from the benefit of observation. There is no antecedent experience to guide or to enlighten us. It is not for man to assume what is right, or proper, or natural for the Almighty to do. It is not in the mere spirit of piety that we say so; it is in the spirit of the soundest experimental philosophy. The argument of the Christian is precisely what the maxims of Lord Bacon would dispose us to acquiesce in. The argument of the infidel is precisely that argument which the same maxims would dispose us to reject; and when put by

the side of the Christian argument, it appears as crude and as unphilosophical, as do the ingenious speculations of the schoolmen, when set in opposition to the rigour, and evidence, and precision, which reign in every department of modern science.

171. The application of Lord Bacon's philosophy to the study of external nature was a happy epoch in the history of physical science. It is not long since this application has been extended to the study of moral and intellectual phenomena. All that we contend for is, that our subjects should have the benefit of the same application; and we count it hard, while, in every other department of inquiry, a respect for truth is found sufficient to repress the appetite for system-building; that theology, the loftiest and most inaccessible of all the sciences, should still remain infected with a spirit so exploded, and so unphilosophical; and that the fancy, and theory, and unsupported speculation, so current among the Deists and demi-infidels of the day, should be held paramount to the authority of facts, which have come down to us with a weight of evidence and testimony, that is quite unexampled in the history of ancient times.

172. What is science, but a record of observed phenomena, grouped together according to certain points of resemblance, which have been suggested by an actual attention to the phenomena themselves? We never think of questioning the existence of the phenomena, after we have demonstrated the genuineness and authenticity of the record. After this is demonstrated, the singular or unexpected nature of the phenomena is not suffered to weaken their credibility,—a credibility which can only be destroyed by the authority of our own personal observation, or some other record possessed of equal or superior pretensions. But in none of the inductive sciences is it in the power of a student to verify every thing by his own personal observation. He must put up with the observations of others, brought home to the convictions of his own mind by creditable testimony. In the science of geology, this is eminently the case. In a science of such extent, our principles must be in part founded upon the observations of others, transmitted to us from a distant country. And in a science, the processes of which are so lengthened in point of time, our principles should also in part be founded on the observations of others, transmitted to us from a remote antiquity. Any observations of our own are so limited, both in point of space and of time, that we never think of opposing their authority to the evidence which is laid before us. Our whole attention is directed to the validity of the record; and the moment that this validity is established, we hold it incumbent upon us to submit our minds to the entire and unmodified impression of the testimony contained in it. Now, all that we ask is, that the same process of investigation be observed in theology, which is held to be so sound and so legitimate in other sciences. In a science of such extent, as to embrace the wide domain of moral and intelligent nature, we feel the littleness of that range to which our own personal observations are confined. We shall be glad, not merely of the information transmitted to us from a distant country, but of the authentic information transmitted to us by any other order of beings, in some distant and unknown part of the creation. In a science, too, which has for its object the lengthened processes of the divine administration, we should like if any record of past times could enable us to extend our observations beyond the limits of our own ephemeral experience; and if there are any events of a former age possessed of such a peculiar and decisive character, as would help us to some satisfactory conclusion in this greatest and most interesting of the sciences.

173. On a subject so much above us and beyond us, we would never think of opposing any preconceptions to the evidence of history. We would maintain the humility of the inductive spirit. We would cast about for facts, and events, and appearances. We would offer our minds as a blank surface to every thing that came to them, supported by unexceptionable evidence. It is not upon the nature of the facts themselves, that we would pronounce upon their credibility, but upon the nature of that testimony by which they were supported. Our whole attention would be directed to the authority of the record. After this was established, we would surrender our whole understanding to its contents. We would school down every antipathy within us, and disown it as a childish affection, unworthy of a philosopher who professes to follow truth through all the disgusts and discouragements which surround it. There are men of splendid reputation in our enlightened circles, who never attended to this speculation, and who annex to the gospel of Christ nothing else than ideas of superstition and vulgarity. In braving their contempt, we would feel ourselves in the best element for the display and exercise of the philosophical temper. We would rejoice in the omnipotence of truth, and anticipate, in triumph, the victory which it must accomplish over the pride of science and the fastidiousness of literature. It would not be the enthusiasm of a visionary which would support us, but the inward working of the very same principle which sustained Galileo, when he adhered to the result of his experiments, and Newton, when he opposed his measurements and observations to the tide of prejudice he had to encounter from the prevailing taste and philosophy of the times.

174. We conceive, that inattention to the above principles has led many of the most popular and respected writers in the Deistical controversy to introduce a great deal of discussion that is foreign to the merits of the question altogether; and in this way the attention is often turned away from the point in which the main strength of the argument lies. An infidel, for example, objects against one of the peculiar doctrines of Christianity. To repel the objection, the Christian conceives it necessary to vindicate the reasonableness of that doctrine, and to shew how consistent it is with all those antecedent conceptions which we derived from the light of natural religion. All this we count superfluous. It is imposing an unnecessary task upon ourselves. Enough for us to have established the authority of the Christian revelation upon the ground of its historical evidence. All that remains is to submit our minds to the fair interpretation of Scripture. Yes; but how do you dispose of the objection drawn from the light of natural religion? In precisely the same way that we would dispose of an objection drawn from some speculative system, against the truth of any physical fact that has been well established by observation or testimony. We would disown the system, and oppose the obstinacy of the fact to all the elegance and ingenuity of the speculation.

175. We are sensible that this is not enough to satisfy a numerous class of very sincere and well-disposed Christians. There are many of this description, who, antecedent to the study of the Christian revelation altogether, repose a very strong confidence in the light of natural religion, and think that, upon the mere strength of its evidence, they can often pronounce with a considerable degree of assurance on the character of the divine administration. To such as these something more

is necessary than the external evidences on which Christianity rests. You must reconcile the doctrines of Christianity with those previous conceptions which the light of nature has given them; and a great deal of elaborate argument is often expended in bringing about this accommodation. It is, of course, a work of greater difficulty, to make Christians of this description of people, though, in point of fact, this difficulty has been overcome, in a way the most masterly and decisive, by one of the soundest and most philosophical of our theologians.

176. To another description of Christians, this attempt to reconcile the doctrines of Christianity with the light of natural religion is superfluous. Give them historical evidence for the truth of Christianity, and all that natural religion may have taught them will fly like so many visionary phantoms before the light of its overbearing authority. With them the argument is reduced to a narrower compass. Is the testimony of the apostles and first Christians sufficient to establish the credibility of the facts which are recorded in the New Testament? The question is made to rest exclusively on the character of this testimony, and the circumstances attending it, and no antecedent theology of their own is suffered to mingle with the investigation. If the historical evidence of Christianity is found to be conclusive, they conceive the investigation to be at an end; and that nothing remains on their part, but an act of unconditional submission to all its doctrines.

177. Though it might be proper, in the present state of opinion, to accommodate to both these cases, yet we profess ourselves to belong to the latter description of Christians. We hold by the total insufficiency of natural religion to pronounce upon the intrinsic merits of any revelation, and think that the authority of every revelation rests exclusively upon its external evidences, and upon such marks of honesty in the composition itself as would apply to any human performance. We rest this opinion, not upon any fanatical expression of the ignorance of man, or how sinful it is for a weak and guilty mortal to pronounce upon the counsels of heaven, and the laws of the divine administration; we disown this presumption, not merely because it is sinful, but because we conceive it to be unphilosophical, and precisely analogous to that theorising *a priori* spirit, which the wisdom of Bacon has banished from all the schools of philosophy.

178. For the satisfaction of the first class, we refer them to that argument which has been prosecuted with so much ability and success by Bishop Butler, in his Analogy of Natural and Revealed Religion. It is not so much the object of this author to found any positive argument on the accordancy which subsists between the processes of the divine administration in nature, and the processes ascribed to God by revelation, as to repel the argument founded upon their supposed discordancy. To one of the second class, the argument of Bishop Butler is not called for; but as to one of the first class, we can conceive nothing more calculated to quiet his difficulties. He believes a God, and he must therefore believe the character and existence of God to be reconcileable with all that he observes in the events and phenomena around him. He questions the claims of the New Testament to be a revelation from heaven; because he conceives, that it ascribes a plan and an economy to the Supreme Being, which are unworthy of his character. We offer no positive solution of this difficulty. We profess ourselves to be too little acquainted with the character of God; and that in this little corner of his works, we see not far enough to offer any decision on the merits of a government, which embraces worlds, and reaches eternity. We think we do enough, if we give a sufficiency of external proof for the New Testament being a true and authentic message from heaven; and that therefore nothing remains for us, but to attend and to submit to it. But the argument of Bishop Butler enables us to do still more than this. It enables us to say, that the very thing objected against in Christianity exists in nature; and that therefore the same God who is the author of nature, may be the author of Christianity. We do not say that any positive evidence can be founded upon this analogy. But in as far as it goes to repel the objection, it is triumphant. A man has no right to retain his theism, if he rejects Christianity upon difficulties to which natural religion is equally liable. If Christianity tells us, that the guilt of a father has brought suffering and vice upon his posterity, it is what we see exemplified in a thousand instances amongst the families around us. If it tells us, that the innocent have suffered for the guilty, it is nothing more than what all history and all observation have made perfectly familiar to us. If it tells us of one portion of the human race being distinguished by the sovereign will of the Almighty for superior knowledge, or superior privileges, it only adds one inequality more to the many inequalities which we perceive every day in the gifts of nature, of fortune, and of providence. In short, without entering into all the details of that argument, which Butler has brought forward in a way so masterly and decisive, there is not a single impeachment which can be offered against the God of Christianity, that may not, if consistently proceeded upon, be offered against the God of Nature itself; if the one be unworthy of God, the other is equally so; and if, in spite of these difficulties, you still retain the conviction, that there is a God of Nature, it is not fair or rational to suffer them to outweigh all that positive evidence and testimony, which have been adduced for proving that the same God is the God of Christianity also.

179. If Christianity be still resisted, it appears to us that the only consistent refuge is Atheism. The very same peculiarities in the dispensation of the gospel, which lead the infidel to reject it as unworthy of God, go to prove, that nature is unworthy of him, and land us in the melancholy conclusion, that whatever theory can be offered as to the mysterious origin and existence of the things which be, they are not under the dominion of a supreme and intelligent mind. Nor do we look upon Atheism as a more hopeless species of infidelity than Deism, unless in so far as it proves a more stubborn disposition of the heart to resist every religious conviction. Viewed purely as an intellectual subject, we look upon the mind of an Atheist, as in a better state of preparation for the proofs of Christianity than the mind of a Deist. The one is a blank surface, on which evidence may make a fair impression, and where the finger of history may inscribe its credible and well-attested information. The other is occupied with pre-conceptions. It will not take what history offers to it. It puts itself into the same unphilosophical posture, in which the mind of a prejudiced Cartesian opposed its theory of the heavens to the demonstration and measurements of Newton. The theory of the Deist upon a subject, where truth is still more inaccessible, and speculation still more presumptuous, sets him to resist the only safe and competent evidence that can be appealed to. What was originally the evidence of observation, and is now transformed into the evidence of testimony, comes down to us in a series of historical documents, the closest and most consistent that all antiqui-

ty can furnish. It is the unfortunate theory which forms the grand obstacle to the admission of the Christian miracles, and which leads the Deist to an exhibition of himself so unphilosophical, as that of trampling on the soundest laws of evidence, by bringing an historical fact under the tribunal of a theoretical principle. The deistical speculation of Rousseau, by which he neutralised the testimony of the first Christians, is as complete a transgression against the temper and principles of true science, as a category of Aristotle when employed to overrule an experiment in chemistry. But however this be, it is evident, that Rousseau would have given a readier reception to the gospel history, had his mind not been preoccupied with the speculation; and the negative state of Atheism would have been more favourable to the admission of those facts, which are connected with the origin and establishment of our religion in the world.

180. This suggests the way in which the evidence for Christianity should be carried home to the mind of an Atheist. He sees nothing in the phenomena around him, that can warrant him to believe in the existence of a living and intelligent principle, which gave birth and movement to all things. He does not say that he would refuse credit to the existence of God upon sufficient evidence, but he says, that there are not such appearances of design in nature, as to supply him with that evidence. He does not deny the existence of God to be a possible truth; but he affirms, that while there is nothing before him but the consciousness of what passes within, and the observation of what passes without, it remains an assertion destitute of proof, and can have no more effect upon his conviction than any other nonentity of the imagination. There is a mighty difference between *not proven* and *disproven*. We see nothing in the argument of the Atheists which goes farther, than to establish the former sentence upon the question of God's existence. It is altogether an argument *ab ignorantia*; and the same ignorance which restrains them from asserting in positive terms that God exists, equally restrains them from asserting in positive terms that God does not exist. The assertion may be offered, that, in some distant regions of the creation, there are tracts of space which, instead of being occupied like the tracts around us with suns and planetary systems, teem only with animated beings, who, without being supported like us on the firm surface of a world, have the power of spontaneous movements in free spaces. We cannot say that the assertion is not true, but we can say that it is not proven. It carries in it no positive character either of truth or falsehood, and may therefore be admitted on appropriate and satisfying evidence. But till that evidence comes, the mind is in a state entirely neutral; and such we conceive to be the neutral state of the Atheist, as to what he holds to be the unproved assertion of the existence of God.

181. To the neutral mind of the Atheist then, unfurnished as it is with any previous conception, we offer the historical evidence of Christianity. We do not ask him to presume the existence of God. We ask him to examine the miracles of the New Testament merely as recorded events, and to admit no other principle into the investigation, than those which are held to be satisfying and decisive, on any other subject of written testimony. The sweeping principle upon which Rousseau, filled with his own assumptions, condemned the historical evidence for the truth of the gospel narrative, can have no influence on the blank and unoccupied mind of an Atheist. He has no presumptions upon the subject; for to his eye the phenomena of nature sit so loose and unconnected with that intelligent Being, to whom they have been referred as their origin, that he does not feel himself entitled, from these phenomena, to ascribe any existence, any character, any attributes, or any method of administration to such a Being. He is therefore in the last possible condition for submitting his understanding to the entire impression of the historical evidence. These difficulties which perplex the Deists, who cannot recognize in the God of the New Testament the same features and the same principles in which they have invested the God of Nature, are no difficulties to him. He has no God of Nature to confront with that real though invisible power which lay at the bottom of those astonishing miracles, on which history has stamped her most authentic characters. Though the power which presided there should be an arbitrary, an unjust, or a malignant being, all this may startle a Deist, but it will not prevent a consistent Atheist from acquiescing in any legitimate inference, to which the miracles of the gospel, viewed in the simple light of historical facts, may chance to carry him. He cannot bring his antecedent information into play upon this question. He professes to have no antecedent information on the subject; and this sense of his entire ignorance, which lies at the bottom of his Atheism, would expunge from his mind all that is theoretical, and make it the passive recipient of every thing which observation offers to its notice, or which credible testimony has brought down to it of the history of past ages.

182. What then, we ask, does the Atheist make of the miracles of the New Testament? If he questions their truth, he must do it upon grounds that are purely historical. He is precluded from every other ground by the very principle on which he has rested his Atheism; and we therefore, upon the strength of that testimony which has been already exhibited, press the admission of these miracles as facts. If there be nothing then, in the ordinary phenomena of nature, to infer a God, do these extraordinary phenomena supply him with no argument? Does a voice from heaven make no impression upon him? And we have the best evidence which history can furnish, that such a voice was uttered; "This is my beloved Son, in whom I am well pleased." We have the evidence of a fact, for the existence of that very Being from whom the voice proceeded, and the evidence of a thousand facts, a power superior to nature; because, on the impulse of a volition, it did counteract her laws and processes, it allayed the wind, it gave sight to the blind, health to the diseased, and, at the utterance of a voice, it gave life to the dead. The ostensible agent in all these wonderful proceedings are not only credentials of his power, but he gave such credentials of his honesty, as dispose our understanding to receive his explanation of them. We do not avail ourselves of any other principle than what an Atheist will acknowledge. He understands as well as we do, the natural signs of veracity, which lie in the tone, the manner, the countenance, the high moral expression of worth and benevolence, and, above all, in that firm and undaunted constancy, which neither contempt, nor poverty, nor death, could shift from any of its positions. All these claims upon our belief, were accumulated to an unexampled degree in the person of Jesus of Nazareth; and when we couple with them his undoubted miracles, and the manner in which his own personal appearance was followed up by a host of witnesses, who, after a catastrophe which would have proved a death-blow to any cause of imposture, offered themselves to the eye of the public, with the same powers, the same evidence, and the same testimony, it seems impossible to resist his account of the invisible principle, which gave birth and movement to the whole of this wonderful transaction. Whatever

Atheism we may have founded on the common phenomena around us, here is a new phenomenon which demands our attention, the testimony of a man who, in addition to evidence of honesty, more varied and more satisfying than were ever offered by a brother of the species, had a voice from the clouds, and the power of working miracles, to vouch for him. We do not think, that the account which this man gives of himself can be viewed either with indifference or distrust, and the account is most satisfying. “I proceeded forth, and came from God.” “He whom God hath sent speaketh the words of God.” “Even as the Father said unto me so I speak.” He had elsewhere said, that God was his Father. The existence of God is there laid before us, by an evidence altogether distinct from the natural argument of the schools, and it may therefore be admitted in spite of the deficiency of that argument. From the same pure and unquestionable source we gather our information of his attributes. “God is true.” “God is a spirit.” He is omnipotent, “for with God all things are possible.” He is intelligent, “for he knoweth what things we have need of.” He sees all things, and he directs all things, for “the very hairs of our head are numbered,” and “a sparrow falleth not to the ground without his permission.”

182. The evidences of the Christian religion are suited to every species of infidelity. We do not ask the Atheist to furnish himself with any previous conception. We ask him to come as he is, and, upon the strength of his own favourite principle, viewing it as a pure intellectual question, and abstracting from the more unmanageable tendencies of the heart and temper. We conceive his understanding to be in a high state of preparation, for taking in Christianity in a fair, purer, and more scriptural form, than can be expected from those whose minds are tainted and pre-occupied with their former speculations.

183. The remainder of this article shall be devoted to the illustration of a very plain but a very important proposition, viz. That, after having established the New Testament to be a message from God, it behoves us to make an entire and unconditional surrender of our minds, to all the duty and to all the information which it sets before us.

184. There is, perhaps, nothing more thoroughly beyond the cognizance of the human faculties, than the truths of religion and the ways of that mighty and invisible Being who is the object of it; and yet nothing, we will venture to say, has been made the subject of more hardy and adventurous speculation. We make no allusion at present to Deists, who reject the authority of the New Testament, because the plan and the dispensation of the Almighty, which is recorded there, is different from that plan and that dispensation which they have chosen to ascribe to him. We speak of Christians, who profess to admit the authority of this record, but who have tainted the purity of their profession by not acting upon its exclusive authority, who have mingled their own thoughts and their own fancy with its information; who, instead of repairing in every question, and in every difficulty, to the principle of “What readest thou,” have abridged the sovereignty of this principle, by appealing to others, of which we undertake to make out the incompetency; who, in addition to the word of God, talk also of the reason of the thing; or the standard of orthodoxy, and have in fact brought down the Bible from the high place which belongs to it, as the only tribunal to which the appeal should be made, or from which the decision should be looked for.

185. But it is not merely among partizans or the advocates of a system, that we meet with this indifference to the authority of what is written. It lies at the bottom of a great deal of that looseness, both in practice and speculation, which we meet with every day in society, and which we often hear expressed in familiar conversation. Whence that list of maxims which are so indolently conceived, but which, at the same time, are so faithfully proceeded upon? “We have all our passions and infirmities; but we have honest hearts, and that will make up for them. Men are not all cast in the same mould. God will not call us to task too rigidly for our foibles, at least this is our opinion; and God can never be so unmerciful, or so unjust, as bring us to a severe and unforgiving tribunal for the mistakes of the understanding.” Now, it is not licentiousness in general, which we are speaking against. It is against that sanction which it appears to derive from the self-formed maxims of him who is guilty of it. It is against the principle that either an error of doctrine, or an indulgence of passion is to be exempted from condemnation, because it has an opinion of the mind to give it countenance and authority. What we complain of is, that a man no sooner sets himself forward and says, “this is my sentiment,” than he conceives that all culpability is taken away from the error, either of practice or speculation, into which he has fallen; the carelessness with which the opinion has been formed, is of no account in the estimate. It is the mere existence of the opinion, which is plead in vindication, and under the authority of *our maxim*, and *our mode of thinking*, every man conceives himself to have a right to his own way and his own peculiarity.

186. Now this might be all very fair, were there no Bible and no revelation in existence. But it is not fair, that all this looseness, and all this variety, should be still floating in the world, in the face of an authoritative communication from God himself. Had no message come to us from the fountain-head of truth, it were natural enough for every individual mind to betake itself to its own speculation. But a message has come to us, bearing on its forehead every character of authenticity, and is it right now, that the question of our faith, or of our duty, should be committed to the capricious variations of this man's taste or of that man's fancy? Our maxim, and our sentiment! God has put an authoritative stop to all this. He has spoken, and the right or the liberty of speculation no longer remains to us. The question now is, not “What thinkest thou?” In the days of Pagan antiquity, no other question could be put, and the wretched delusions and idolatries of that period let us see what kind of answer the human mind is capable of making, when left to its own guidance, and its own authority. But we call ourselves Christians, and profess to receive the Bible as the directory of our faith, and the only question in which we are concerned, is, “What is written in the law? how readest thou?”

187. But there is a way of escaping from this conclusion. No man calling himself a Christian, will ever disown in words the authority of the Bible. Whatever be counted the genuine interpretation, it must be submitted to. But in the act of coming to this interpretation, it will be observed, there is room for the unwarrantable principles which we are attempting to expose. The business of a scripture critic is to give a fair representation of the sense of all its passages as they exist in the original. Now, this is a process which requires some investigation, and it is during the time that this process is carrying on, that the tendencies and antecedent opinions of the mind are suffered to mislead the enquirer from the true principles of the business in which he is employed.

The mind and meaning of the author, who is translated, is purely a question of language, and should be decided upon no other principles than those of grammar or philology. Now, what we complain of is, that while this principle is recognised and acted upon in every other composition which has come down to us from antiquity, it has been most glaringly departed from in the case of the Bible; that the meaning of its author, instead of being made singly and entirely a question of grammar, has been made a question of metaphysics, or a question of sentiment; that instead of the argument resorted to being, such must be the rendering from the structure of the language, and the import and significancy of its phrases, it has been, such must be the rendering from the analogy of the faith, the reason of the thing, the character of the Divine mind, and the wisdom of all his dispensations. And whether this argument be formally insisted upon or not, we have still to complain, that in reality it has a most decided influence on the understanding of many a Christian; and in this way, the creed which exists in his mind, instead of being a fair transcript of the New Testament, is the result of a compromise which has been made betwixt its authoritative decisions and the speculations of his own fancy.

188. What is the reason why there is so much more unanimity among critics and grammarians about the sense of any ancient author, than about the sense of the New Testament. Because the one is made purely a question of criticism: The other has been complicated with the uncertain fancies of a daring and presumptous theology. Could we only dismiss these fancies, sit down like a school-boy to his task, and look upon the study of divinity as a mere work of translation, then we would expect the same unanimity among Christians that we meet with among scholars and literati about the system of Epicurus or philosophy of Aristotle. But here lies the distinction betwixt the two cases. When we make out, by a critical examination of the Greek of Aristotle, that such was his meaning, and such his philosophy, the result carries no authority with it, and our mind retains the congenial liberty of its own speculations. But if we make out, by a critical examination of the Greek of St Paul, that such is the theology of the New Testament, we are bound to submit to this theology; and our minds must surrender every opinion, however dear to them. It is quite in vain to talk of the mysteriousness of the subject, as being the cause of the want of unanimity among Christians. It may be mysterious, in reference to our former conceptions. It may be mysterious in the utter impossibility of reconciling it with our own assumed fancies, and self-formed principles. It may be mysterious in the difficulty which we feel in comprehending the manner of the doctrine, when we ought to be satisfied with the authoritative revelation which has been made to us of its existence and its truth. But if we could only abandon all our former conceptions, if we felt that our business was to submit to the oracle of God, and that we are not called upon to effect a reconciliation betwixt a revealed doctrine of the Bible, and an assumed or excogitated principle of our own;—then we are satisfied, that we would find the language of the Testament to have as much clear, and precise, and distinctive simplicity, as the language of any sage or philosopher that has come down to our time.

189. Could we only get it reduced to a mere question of language, we should look at no distant period for the establishment of a pure and unanimous Christianity in the world. But, no. While the mind and the reasoning of any philosopher is collected from his words, and these words tried as to their import and significancy upon the appropriate principles of criticism, the mind and the reasoning of the spirit of God is not collected upon the same pure and competent principles of investigation. In order to know the mind of the Spirit, the communications of the Spirit, and the expression of these communications in written language, should be consulted. These are the only data upon which the enquiry should be instituted. But, no. Intead of learning the designs and character of the Almighty from his own mouth, we sit in judgment upon them, and make our conjecture of what they should be, take the precedency of his revelations what they are. We do Him the same injustice that we do to an acquaintance, whose proceedings and whose intentions we venture to pronounce upon, while we refuse him a hearing, or turn away from the letter in which he explains himself. No wonder, then, at the want of unanimity among Christians, so long as the question of "what thinkest thou?" is made the principle of their creed, and, for the sake of criticism, they have committed themselves to the endless caprices of the human intellect. Let the principle of "what thinkest thou" be exploded, and that of "what readest thou" be substituted in its place. Let us take our lesson as the Almighty places it before us, and, instead of being the judge of his conduct, be satisfied with the safer and humbler office of being the interpreter of his language.

190. Now this principle is not exclusively applicable to the learned. The great bulk of Christians have no access to the Bible in its original languages; but they have access to the common translation, and they may be satisfied by the concurrent testimony of the learned among the different sectaries of this country, that the translation is a good one. We do not confine the principle to critics and translators, we press it upon all. We call upon them not to form their divinity by independent thinking, but to receive it by obedient reading, to take the words as they stand, and submit to the plain English of the scriptures which lie before them. It is the office of a translator to give a faithful representation of the original. Now that this faithful representation has been given, it is our part to peruse it with care, and to take a fair and a faithful impression of it. It is our part to purify our understanding of all its previous conceptions. We must bring a free and unoccupied mind to the exercise. It must not be the pride or the obstinacy of self formed opinions, or the haughty independence of him, who thinks he has reached the manhood of his understanding. We must bring with us the docility of a child, if we want to gain the kingdom of heaven. It must not be a partial but an entire and unexpected obedience, There must be no garbling of that which is entire, no darkening of that which is luminous, no softening down of that which is authoritative or severe. The Bible will allow of no compromise. It professes to be the directory of our faith, and claims a total ascendency over the souls and the understandings of men. It will enter into no composition with us or our natural principles. It challenges the whole mind as its due, and it appeals to the truth of heaven for the high authority of its sanctions. "Whosoever addeth to, or taketh from, the words of this book, is accursed," is the absolute language in which it delivers itself. This brings us to its terms. There is no way of escaping after this. We must bring every thought into the captivity of its obedience, and, as closely as ever lawyer stuck to his document or his extracts, must we abide by the rule and the doctrine which this authentic memorial of God sets before us.

191. Now we hazard the assertion, that, with a number of professing Christians, there is not this unexcepted submission of the understanding to the authority of the Bible; and that the authority of the Bible is often modified, and in some cases superseded by the authority of other principles. One of these principles is the reason of the thing. We do not know if this principle would be at all felt or appealed to by the earliest Christians. They turned from dumb idols to serve the living and the true God. There was nothing in their antecedent theology which they could have any respect for: Nothing which they could confront, or bring into competition with the doctrines of the New Testament. In these days, the truth as it is in Jesus came to the mind of its disciples, recommended by its novelty, by its grandeur, by the power and recency of its evidences, and above all by its vast and evident superiority over the fooleries of a degrading Paganism. It does not occur to us, that men in these circumstances would ever think of sitting in judgment over the mysteries of that sublime faith which had charmed them into an abandonment of their earlier religion. It rather strikes us, that they would receive them passively; that, like scholars who had all to learn, they would take their lesson as they found it; that the information of their teachers would be enough for them; and that the restless tendency of the human mind to speculation, would for a time find ample enjoyment in the rich and splendid discoveries, which broke like a flood of light upon the world. But we are in different circumstances. To us, these discoveries, rich and splendid as they are, have lost the freshness of novelty. The sun of righteousness, like the sun in the firmament, has become familiarized to us by possession. In a few ages, the human mind deserted its guidance, and rambled as much as ever in quest of new speculations. It is true, that they took a juster and a loftier flight since the days of Heathenism. But it was only because they walked in the light of revelation. They borrowed of the New Testament without acknowledgment, and took its beauties and its truths to deck their own wretched fancies and self-constituted systems. In the process of time, the delusion multiplied and extended. Schools were formed, and the way of the Divinity was as confidently theorized upon, as the processes of chemistry, or the economy of the heavens. Universities were endowed, and natural theology took its place in the circle of the sciences. Folios were written, and the respected luminaries of a former age poured their *à priori* and their *à posteriori* demonstrations on the world. Taste, and sentiment, and imagination, grew apace; and every raw untutored principle which poetry could clothe in prettiness, or over which the hand of genius could throw the graces of sensibility and elegance, was erected into a principle of the divine government, and made to preside over the councils of the deity. In the mean time, the Bible, which ought to supersede all, was itself superseded. It was quite in vain to say that it was the only authentic record of an actual embassy which God had sent into the world. It was quite in vain to plead its testimonies, its miracles, and the unquestionable fulfilment of its prophecies. These mighty claims must be over, and be suspended, till we have settled—what? The reasonableness of its doctrines. We must bring the theology of God's ambassador to the bar of our self-formed theology. The Bible, instead of being admitted as the directory of our faith upon its external evidences, must be tried upon the merits of the work itself; and if our verdict be favourable, it must be brought in, not as a help to our ignorance, but as a corollary to our demonstrations. But is this ever done? Yes! by Dr Samuel Clarke, and a whole host of followers and admirers. Their first step in the process of theological study, is to furnish their minds with the principles of natural theology. Christianity, before its external proofs are looked at or listened to, must be brought under the tribunal of those principles. All the difficulties which attach to the reason of the thing, or the fitness of the doctrines, must be formally discussed, and satisfactorily got over. A voice was heard from heaven, saying of Jesus Christ, "This is my beloved Son, hear ye him." The men of Galilee saw him ascend from the dead to the heaven which he now occupies. The men of Galilee gave their testimony; and it is a testimony which stood the fiery trial of persecution in a former age, and of sophistry in this. And yet, instead of hearing Jesus Christ as disciples, they sit in authority over him as judges. Instead of forming their divinity after the Bible, they try the Bible by their antecedent divinity; and this book, with all its mighty train of evidences, must drivel in their antichambers, till they have pronounced sentence of admission, when they have got its doctrines to agree with their own airy and unsubstantial speculations.

192. We do not condemn the exercise of reason in matters of theology. It is the part of reason to form its conclusions, when it has data and evidences before it. But it is equally the part of reason to abstain from its conclusions when these evidences are wanting. Reason can judge of the external evidences for Christianity, because it can discern the merits of human testimony; and it can perceive the truth or the falsehood of such obvious credentials in the performance of a miracle, or the fulfilment of a prophecy. But reason is not entitled to sit in judgment over these internal evidences, which many a presumptuous theologian has attempted to derive from the reason of the thing, or from the agreement of the doctrine with the fancied character and attributes of the Deity. One of the most useful exercises of reason, is to ascertain its limits, and to keep within them; to abandon the field of conjecture, and to restrain itself within that safe and certain barrier which forms the boundary of human experience. However humiliating you may conceive it, it is this that lies at the bottom of Lord Bacon's philosophy, and it is to this that modern science is indebted for all her solidity and all her triumphs. Why does philosophy flourish in our days? Because her votaries have learned to abandon their own creative speculations, and to submit to evidences, let her conclusions be as painful and as unpalatable as they will. Now all that we want, is to carry the same lesson and the same principle to theology. Our business is not to guess, but to learn. After we have established Christianity to be an authentic message from God upon these historical grounds,—when the reason and experience of man entitle him to form his conclusions,—nothing remains for us, but an unconditional surrender of the mind to the subject of the message. We have a right to sit in judgment over the credentials of heaven's ambassador, but we have no right to sit in judgment over the information he gives us. We have no right either to refine or to modify that information, till we have accommodated it to our previous conceptions. It is very true, that if the truths which he delivered lay within the field of human observation, he brings himself under the tribunal of our antecedent knowledge. Were he to tell us, that the bodies of the planetary system moved in orbits which are purely circular, we would oppose to him the observations and measurements of astronomy. Were he to tell us, that in winter the sun never shone, and that in summer no

cloud ever darkened the brilliancy of his career, we would oppose to him the certain remembrances, both of ourselves and of our whole neighbourhood. Were he to tell us, that we were perfect men, because we were free from passion, and loved our neighbours as ourselves, we would oppose to him the history of our own lives, and the deeply-seated consciousness of our own infirmities. On all these subjects, we can confront him; but when he brings truth from a quarter which no human eye ever explored; when he tells us the mind of the Deity, and brings before us the counsels of that invisible Being, whose arm is abroad upon all nations, and whose views reach to eternity, he is beyond the ken of eye or of telescope, and we must submit to him. We have no more right to sit in judgment over his information, than we have to sit in judgment over the information of any other visitor who lights upon our planet, from some distant and unknown part of the universe, and tells us what worlds roll in these remote tracts which are beyond the limits of our astronomy, and how the Divinity peoples them with his wonders. Any previous conception of ours are of no more value than the fooleries of an infant; and should we offer to resist or modify upon the strength of our conceptions, we would be as unsound and as unphilosophical as ever schoolman was with his categories, or Cartesian with his whirlpools of ether.

193. Let us go back to the first Christians of the Gentile world. They turned from dumb idols to serve the living and the true God. They made a simple and entire transition from a state as bad, if not worse, than that of entire ignorance, to the Christianity of the New Testament. Their previous conceptions, instead of helping them, behoved to be utterly abandoned; nor was there that intermediate step which so many of us think to be necessary, and which we dignify with the name of the rational theology of nature. In these days, this rational theology was unheard of; nor have we the slightest reason to believe that they were ever initiated into its doctrines, before they were looked upon as fit to be taught the peculiarities of the gospel. They were translated at once from the absurdities of Paganism to that Christianity which has come down to us, in the records of evangelical history, and the epistles which their teachers addressed to them. They saw the miracles; they acquiesced in them, as satisfying credentials of an inspired teacher; they took the whole of their religion from his mouth; their faith came by hearing, and hearing by the words of a divine messenger. This was their process, and it ought to be ours. We do not see the miracles, but we see their reality through the medium of that clear and unsuspicious testimony which has been handed down to us. We should admit them as the credentials of an embassy from God. We should take the whole of our religion from the records of this embassy; and, renouncing the idolatry of our own self-formed conceptions, we should repair to that word, which was spoken to them that heard it, and transmitted to us by the instrumentality of written language. The question with them was, What hearest thou? The question with us is, What readest thou? They had their idols, and they turned away from them. We have our fancies, and we contend, that, in the face of an authoritative revelation from heaven, it is as glaring idolatry in us to adhere to these, as it would be were they spread out upon canvass, or chiselled into material form by the hands of a statuary.

194. In the popular religions of antiquity, we see scarcely the vestige of a resemblance to that academical theism which is delivered in our schools, and figures away in the speculations of our moralists. The process of conversion among the first Christians was a very simple one. It consisted of an utter abandonment of their heathenism, and an entire submission to those new truths which came to them through the revelation of the gospel, and through it only. It was the pure theology of Christ and of his Apostles. That theology which struts in fancied demonstration from a professor's chair, formed no part of it. They listened as if they had all to learn: we listen as if it was our office to judge, and to give the message of God its due place and subordination among the principles which we had previously established. Now these principles were utterly unknown at the first publication of Christianity. The Galatians, and Corinthians, and Thessalonians, and Philippians, had no conception of them. And yet, will any man say, that either Paul himself, or those who lived under his immediate tuition, had not enough to make them accomplished Christians, or that they fell short of our enlightened selves, in the wisdom which prepares for eternity, because they wanted our rational theology as a stepping-stone to that knowledge which came, in pure and immediate revelation, from the Son of God. The gospel was enough for them, and it should be enough for us also. Every natural or assumed principle which offers to abridge its supremacy, or even so much as to share with it in authority and direction, should be instantly discarded. Every opinion in religion should be reduced to the question of—what readest thou? and the Bible be acquiesced in, and submitted to, as the alone directory of our faith, where we can get the whole will of God for the salvation of men.

195. But is not this an enlightened age; and, since the days of the gospel, has not the wisdom of two thousand years accumulated upon the present generation? has not science been enriched by discovery? and is not theology one of the sciences? Are the men of this advanced period to be restrained from the high exercise of their powers? and, because the men of a remote and barbarous antiquity lisped and drivelled in the infancy of their acquirements, is that any reason why we should be restricted like so many school-boys to the lesson that is set before us? It is all true that this is a very enlightened age, but on what field has it acquired so flattering a distinction? On the field of experiment. The human mind owes all its progress to the confinement of its efforts within the safe and certain limits of observation, and to the severe restraint which it has imposed upon its speculative tendencies. Go beyond these limits, and the human mind has not advanced a single inch by its own independent exercises. All the philosophy which has been reared by the labour of successive ages, is the philosophy of facts reduced to general laws, or brought under a general description from observed points of resemblance. A proud and a wonderful fabric we do allow; but we throw away the very instrument by which it was built the moment that we cease to observe, and begin to theorize and excogitate. Tell us a single discovery, which has thrown a particle of light on the details of the divine administration. Tell us a single truth in the whole field of experimental science, which can bring us to the moral government of the Almighty by any other road than his own revelation. Astronomy has taken millions of suns and of systems within its ample domain; but the ways of God to man stand at a distance as inaccessible as ever. Nor has it shed so much as a glimmering over the councils of that mighty and invisible Being, who sits in high authority over all worlds. The boasted discoveries of modern science are all confined to that field, within which the sense of man can expatiate. The moment we go beyond this field they cease to be discoveries, and

are the mere speculations of the fancy. The discoveries of modern science have, in fact, imparted a new energy to the sentiment in question. They all serve to exalt the Deity, but they do not contribute a single iota to the explanation of his purposes. They make him greater, but they do not make him more comprehensible. He is more shrouded in mystery than ever. It is not himself whom we see, it is his workmanship; and every new addition to its grandeur or to its variety which philosophy opens to our contemplation, throws our understanding at a greater distance than before, from the mind and conception of the sublime Architect. Instead of the God of a single world, we now see him presiding in all the majesty of his high attributes, over a mighty range of innumerable systems. To our little eye he is wrapt in more awful mysteriousness, and every new glimpse which astronomy gives us of the universe, justifies, to the apprehension of our mind, that impassable barrier which stands between the counsels of its Sovereign, and those fugitive beings who strut their evanescent hour in the humblest of its mansions. If this invisible Being would only break that mysterious silence in which he has wrapt himself, we feel that a single word from his mouth would be worth a world of darkling speculations. Every new triumph which the mind of man achieves in the field of discovery, binds us more firmly to our Bible; and by the very proportion in which philosophy multiplies the wonders of God, do we prize that book, in which the evidence of history has stamped the character of his authentic communication.

196. The course of the moon in the heavens has exercised astronomers for a long series of ages, and now that they are able to assign all the irregularities of its periods, it may be counted one of the most signal triumphs of modern science. The question lay within the limits of the field of observation. It was accessible to measurement, and, upon the sure principles of calculation, men of science have brought forward the confident solution of a problem, the most difficult and trying that ever was submitted to the human intellect. But let it never be forgotten, that those very maxims of philosophy which guided them so surely and so triumphantly within the field of observation, also restrained them from stepping beyond it, and though none were more confident than they whenever they had evidence and experiment to enlighten them, yet none were more scrupulous in abstaining to pronounce upon any subject, where evidence and experiment were wanting. Let us suppose that one of their number, flushed with the triumph of success, passed on from the work of calculating the periods of the moon, to theorise upon its chemical constitution; the former question lies within the field of observation, the other is most thoroughly beyond it; and there is not a man, whose mind is disciplined to the rigour and sobriety of modern science, that would not look upon the theory with the same contempt, as if it were the dream of a poet, or the amusement of a schoolboy. We have heard much of the moon, and of the volcanoes which blaze upon its surface. Let us have incontestible evidence, that a falling stone proceeds from the eruption of one of these volcanoes, and the chemistry of the moon will receive more illustration from the analysis of that stone, than from all the speculations of all the theorists. It brings the question in part within the limits of observation. It soon becomes a fair subject for the exercise of the true philosophy. The eye can now see, and the hand can now handle it; and the information furnished by the laborious drudgery of experimental men, will be received as a truer document, than the theory of any philosopher, however ingenious, or however splendid.

197. At the hazard of being counted whimsical, we bring forward the above as a competent illustration of the principle which we are attempting to establish. We do all homage to modern science, nor do we dispute the loftiness of its pretensions. But we maintain, that however brilliant its career in those tracts of philosophy, where it has the light of observation to conduct it, the philosophy of all that lies without the field of observation is as obscure and inaccessible as ever. We maintain, that to pass from the motions of the moon to an unauthorized speculation upon the chemistry of its materials, is a presumption disowned by philosophy. We ought to feel, that it would be a still more glaring transgression of all its maxims, to pass from the brightest discovery in the catalogue, to the ways of that mysterious Being, whom no eye hath seen, and whose mind is capacious as infinity. The splendour and the magnitude of what we do know, can never authorise us to pronounce upon what we do not know; nor can we conceive a transition more ardent or more insurmountable, than to pass from the truths of natural science to a speculation on the details of God's administration, or the economy of his moral government. We hear much of revelations from heaven. Let any one of these bear the evidence of an actual communication from God himself, and all the reasonings of all the theologians must vanish, and give place to the substance of this communication. Instead of theorising upon the nature and properties of that divine light which irradiates the throne of God, and exists at so immeasurable a distance from our faculties, let us point our eyes to that emanation, which has actually come down to us. Instead of theorising upon the councils of the divine mind, let us go to that volume which lighted upon our world nearly two thousand years ago, and which bears the most authentic evidence, that it is the depository of part of these councils. Let us apply the proper instrument to this examination. Let us never conceive it to be a work of speculation or fancy. It is a pure work of grammatical analysis. It is an unmixed question of language. The commentator who opens this book with the one hand, and carries his system in the other, has nothing to do with it. We admit of no other instrument than the vocabulary and the lexicon. The man whom we look to is the scripture critic, who can appeal to his authorities for the import and significancy of phrases, and whatever be the strict result of his patient and profound philology, we submit to it. We call upon every enlightened disciple of Lord Bacon to approve the steps of this process, and to acknowledge, that the same habits of philosophising to which science is indebted for all her elevation in those latter days, will lead us to cast down all our lofty imaginations, and bring every thought into the captivity of the obedience of Christ.

198. But something more remains to be done. The mind may have discernment enough to acquiesce in the speculative justness of a principle; but it may not have vigour or consistency enough to put it into execution. Lord Bacon pointed out the method of true philosophising; yet, in practice, he abandoned it, and his own physical investigations may be ranked among the most effectual specimens of that rash and unfounded theorising, which his own principles have banished from the schools of philosophy. Sir Isaac Newton completed in his own person the character of the true philosopher. He not only saw the general principle, but he obeyed it. He both betook himself to the drudgery of observation, and

he endured the pain which every mind must suffer in the act of renouncing its old habits of conception. We call upon our readers to have manhood and philosophy enough to make a similar sacrifice. It is not enough, that the Bible be acknowledged as the only authentic source of information respecting the details of that moral economy, which the Supreme Being has instituted for the government of the intelligent beings who occupy this globe. Its authenticity must be something more than acknowledged. It must be felt, and, in act and obedience, submitted to. Let us put them to the test. "Verily I say unto you," says our Saviour, "unless a man shall be born again, he shall not enter into the kingdom of God." "By grace ye are saved through faith, and that not of yourselves, it is the gift of God." "Justified freely by his grace through the redemption that is in Christ Jesus, whom God has set forth to be a propitiation through faith in his blood." We need not multiply quotations; but if there be any repugnance to the obvious truths which we have announced to the reader in the language of the Bible, his mind is not yet tutored to the philosophy of the subject. It may be in the way, but the final result is not yet arrived at. It is still a slave to the elegance or the plausibility of its old speculations; and though it admits the principle, that every previous opinion must give way to the supreme authority of an actual communication from God, it wants consistency and hardihood to carry the principle into accomplishment. (T. C.)

CHRISTIANSTADT, a town of Sweden, and the capital of the province of Schonen or Scania, was built in 1614 by Christian IV. king of Denmark, but ceded to Sweden by the treaty of Roschild in 1658. "The town," says Mr Coxe, "is small, but neatly built, and is esteemed the strongest fortress in Sweden. The houses are all of brick, and mostly stuccoed white. It stands in a marshy plain, close to the river Helge-a, which flows into the Baltic at Ahus, at the distance of twenty miles, and is navigable only for small craft of seven tons burthen. English vessels annually resort to this port for alum, pitch, and tar. The inhabitants have manufactures of cloth and silken stuffs, and carry on a small degree of commerce." Kuttner represents Christianstadt as a wretched disagreeable place, containing none of the good houses which are seen in the Swedish towns, and exhibiting none of that opulence which manufactures generally diffuse. The chief public buildings are the arsenal, the governor's house, the principal church, and the bridge. Population 1980. According to a trigonometrical survey, it is situated in 14° 10′ East Long. and 56° 1′ 15″ North Lat. See Coxe's *Travels in Poland, Russia, and Sweden*, vol. iv. p. 289; Kuttner's *Travels through Denmark, Sweden*, Lett. X.; Reichard's *Guide des Voyageurs, &c.* vol. i. p. 99, 4th edit. (*w*)

CHRISTINA, in biography, a celebrated queen of Sweden, the daughter and only child of the great Gustavus Adolphus. When her father fell in the battle of Lutzen, in 1632, she was only five years of age. The affairs of her kingdom, however, went on prosperously under the superintendance of the Chancellor Oxenstiern, and by the conduct and bravery of the able generals who at that time commanded in the Swedish armies. By this means, the preponderancy which Sweden had acquired in the Protestant league, under the reign of Gustavus, was preserved undiminished during the minority of Christina.

At a very early age, this princess discovered an invincible antipathy for the employments and conversation of her own sex, of which she takes notice in her memoirs; and she had the natural awkwardness of a man, with respect to the little occupations which are appropriate to females. On the other hand, she was passionately fond of violent exercise, and the amusements which consist in feats of strength and agility. Her studies, too, were of the masculine order; and she made no mean proficiency in the abstract sciences, and in the learned languages. At an early age, she was versant in legislation and government, and able to read the Greek historians in the original. As she advanced in years, the love of letters seems to have become her ruling passion; and had a powerful influence on the fortune of her future life.

The general peace of Westphalia, in 1648, restored tranquillity to Europe; and was concluded on terms which were sufficiently honourable to Sweden, at that time in the zenith of its military reputation. A few years previous to this event, Christina had assumed the reins of government at the early age of eighteen, and proved herself fully able to conduct the affairs of a powerful kingdom. It is not, therefore, to be wondered at, that about this period almost all the princes of Europe aspired to the honour of her hand. Among others were the kings of Spain and Poland, the king of the Romans, the prince of Denmark, the Elector Palatine, the elector of Brandenburg, Don John of Austria, and Charles Gustavus, Count Palatine, her own first cousin, and heir-apparent to the crown. She was deaf, however, to all their proposals, as well as to the anxious solicitations of her people; pleading as the motives of her refusal, diversity of political interests, of manners, or of religion. When pressed more closely by her subjects, she made no scruple to avow an insuperable aversion to matrimony; declaring, "that there were certain duties required by the nuptial ceremony, with which she could not persuade herself to comply." Her high spirit, probably, could not brook that subjection which is entailed by the matrimonial tie upon the female sex. To prove how much she was in earnest in her resolution, she solemnly appointed Gustavus her successor; but without admitting him to any participation in the rights of the crown during her own life. Her vow of celibacy in no degree diminished the attachment which, at this period, she received from her subjects; and which was powerfully evinced, by the general expression of joy at a narrow escape which she made from assassination by the hand of a madman, as she was assisting at a public act of devotion in the chapel of the castle of Stockholm, which was in a great measure due to her own intrepidity and presence of mind. Not long after, the life of the queen was exposed to a no less imminent danger by an accident, from which she also had the good fortune to escape unhurt. Having given orders for some ships of war to be equipped at the port of Stockholm, she went to inspect them when they were finished; but as she was going on board, across a narrow plank, the foot of her conductor, Admiral Fleming, slipped, and in his fall he drew the queen along with him, into a part of the sea which was nearly 90 feet deep. The queen's first equerry, Anthony Steinberg, instantly threw himself into the water, laid hold of her robe, and, with such assistance as was at hand, fortunately dragged her on shore. During this accident, her recollection was such, that the moment her head was above water, she cried out, "Take care of the admiral." When she got on dry land, she betrayed no emotion either by her gesture or countenance; and the same day she dined in public, and entertained her company with a humorous account of her adventure.

In the year 1650, Christina was crowned with great pomp and splendour; and as, at this period, her kingdom enjoyed a state of uninterrupted tranquillity, she felt herself at liberty to gratify her ruling passion for letters; and declared herself the patroness of the learned, and the encourager of the fine arts throughout Europe. She invited to her court, and was anxious to have about her person, all the distinguished characters of her time. Among these we may reckon Grotius, Pascal, Bochart, Descartes, Gassendi, Saumaise, Vossius, Heinsius, Meibornius, Menage, Bayle, Madame Dacier, Filicaia, and many others. Her preference, however, seems to have been directed more by general fame, than by her own judgment, or discrimination of their several excellencies; for Menage stood much higher in her esteem than Descartes, whom she disgusted, and at length wholly neglected. Her want of a just sense of merit was remarkably evinced, by the favour which she shewed to an adventurer called Michon, but better known by the name of *Bourdelot*, who was brought to court by the learned Saumaise; but had little to recommend him, except his sprightliness and buffoonery. This unworthy minion, not only took place of true literary merit at the Swedish court, but was able to supplant, in the favour of the queen, Count Magnus de la Gardie, son of the constable of Sweden, who was a relation, a favourite, and a reputed lover of Christina. She was compelled, however, by the public indignation, to banish Bourdelot; and he was no sooner gone, than her regard for him seemed to cease. So lavish was Christina in her gifts to her literary favourites, and so profuse in her collection of books, manuscripts, medals, paintings, and antiques, that she brought the finances of her kingdom into considerable disorder.

At first Christina appeared attached to the duties of a sovereign; but two years had scarcely elapsed from the period of her coronation, when, with a characteristic fickleness, she became disgusted with the fatigues and embarrassments of royalty; and determined to abdicate the crown, and, in private life, to enjoy independence and literary ease. In 1652, she communicated her resolution to the senate; but was prevailed upon, by their remonstrances, in which her successor Gustavus joined, to relinquish her intention. Finding, however, her repugnance at reigning rather increase than diminish, she finally effected her purpose in 1654, when she was only in her twenty-eighth year; although it appears by one of her letters to M. Canut, that she had meditated this project eight years before, and communicated it to him five years before it took place. The fickleness of Christina was still further evinced, by her abjuring her religion, at the same time that she abdicated her crown. Her declaring herself a papist necessarily gave great disgust to her Protestant subjects; but was a mighty triumph for the Romanists.

Immediately after her abdication, Christina quitted Sweden, exhibiting the greatest joy on being now the uncontrouled mistress of her actions. When she came to a little brook, which separates Sweden from Denmark, she got out of her carriage, and, leaping on the other side, exclaimed in a transport of delight, "At last I am free, and out of Sweden, whither, I hope, I shall never return." She now dismissed her female attendants, and even laid aside the habit of her sex. "I would become a man (said she); yet I do not love men, because they are men, but because they are not women." The same inconsistency of temper, however, still continued to actuate Christina, and induced her to shift continually from place to place. She first took up her abode at Brussels; from thence she went to Rome; from Rome to France; and from France she went to Rome again. She also visited Hamburgh; and went twice to Sweden, where she was by no means well received.

While in France, she was treated with much respect by the court; and had apartments assigned her by Louis XIV. at Fontainbleau. But she soon disgusted the Parisians, by her violation of the manners of the country, which she affected to treat with great ridicule, and by the rudeness and indelicacy of her conversation. It was here, also, that she committed an action, which has affixed an indelible stain upon her memory, the murder of her master of the horse, Monaldeschi, who, having on some account incurred her displeasure, was stabbed by her order, by two of her domestics, in an apartment adjoining that in which she herself was. After this, Christina became sensible that she was regarded with horror in France, and would gladly have visited England; but received no encouragement for that purpose from Cromwell, who was then in power.

It was on the death of Charles Gustavus in 1660, that she took her first journey to Sweden, being, with characteristic fickleness, inspired by the desire of recovering her crown. Her ancient subjects, however, were altogether indisposed towards her and her new religion, and insisted on a second renunciation of the throne, before they agreed to confirm her revenues. In 1662, some differences with the Pope, and the ill payment of her appointments, induced her again to visit her native country; but the conditions annexed by the senate to her residence there rendered her stay very short. She then went to Rome, where she resided with little interruption till her death in 1689. During this interval, she cultivated a correspondence with the learned men all over Europe; but her restless disposition led her, at the same time, to intrigue in all the political cabals of the times. Though she had resigned the crown of Sweden, she canvassed for that of Poland. At the peace of Nimeguen, she sent a plenipotentiary to take care of her interests, who with difficulty procured the remittance of her arrears. During the civil contest in France, called the *Fronde*, she officiously offered her mediation to both parties, conceiving herself capable of reconciling their interests, and calming their passions. On the revocation of the edict of Nantz in 1685, she wrote to the French ambassadors in Sweden, animadverting, with much freedom and good sense, on the folly of making converts by persecution, and the bad policy of banishing useful artizans for a difference in religious faith. Her letter was published by Bayle, at which Christina was greatly offended; but afterwards appeased, on the submission of the philosopher.

Upon the whole, with some striking virtues, this princess had many faults. She had magnanimity, talents, and learning; but she was fickle, violent, intriguing, and revengeful. She says of herself, that she was "mistrustful, ambitious, passionate, haughty, impatient, contemp-

Christopher's.

tuous, satirical, incredulous, undevout, of an ardent and violent temper, and extremely amorous;" a propensity to which, she would have us to understand, her virtue and her pride were always superior. In a letter written to Mademoiselle de Scudery some time before her death, she expresses herself with great tranquillity on the prospect of her approaching end; and she passed the last scene with philosophical composure. She died at the age of sixty-three, leaving behind her many letters; a "Collection of Miscellaneous Thoughts or Maxims;" and "Reflections on the Life and Actions of Alexander the Great." See Coxe's *Travels; Univ. Hist.*; and *Gen. Biog.* See also SWEDEN. (*m*)

CHRISTOPHER'S, ST. or ST KITT'S, is one of the Leeward West India islands, and was called *Liemuiga*, or the Fertile Island, by the Charaibes, by whom it was possessed when discovered by Columbus in 1493, who gave it his own Christian name.

St Christopher's is divided into nine parishes, and contains four towns and villages, viz. the capital Basseterre, which contains above 800 houses, Sandy Point, Old Road, and Deep Bay. The principal fortifications are Fort Charles and Brimstonhill, three batteries at Basseterre, one at Figtreebay, and a fourth at Palmeto Point.

The island is about forty two miles in circumference, and its superficial extent is about 43,726 acres. The interior part of the island consists of naked precipices, and barren mountains, the highest of which is Mount Misery, which is about 3711 feet high, and appears to have been formerly a volcano. The plains, which are extremely fertile, are appropriated to the growth of sugar, and to pasturage, about 17,000 acres being devoted to the former, and 4000 to the latter. Provisions and a little cotton are the only other articles of produce. The average quantity of sugar produced annually is about 16,000 hogsheads of 16 cwt.; and as only one half of the cane land is annually cut, the produce of each acre is about two hogsheads of 16 cwt.—a return which is supposed to exceed that of any other sugar country in the world. The soil of the island is a light and porous dark grey loam, lying above a stratum of gravel, about ten inches deep. From 3000 to 4000 barrels of rum are annually made in the island.

Among the mountains in the centre of St Christopher's, there is one which contains mines of sulphur, and there is another not far distant from Fort Charles, in which there is said to be a mine of silver. In the south-east part of the island there are very fine salt ponds, which produce most excellent salt: One of these is more than a hundred acres in extent, and is surrounded with several lesser ponds, and with a number of small hills.

The following Table contains an accurate statement of the articles exported into St Christopher's in the years 1804, 1805, 1806.

Table of the Articles imported into St Christopher's in the Years 1804, 1805, and 1806.

Articles imported.	Great Britain.	British Colonies.	United States.	Other Countries.

The population of St Christopher's, in 1637, amounted to about 13,000. It contains at present about 20,000 blacks, and 8000 whites. West Long. 63° 17′, North Lat. 17° 15′. See Edward's *Hist. of the West Indies*, and Gray's *Letter from Canada*. See also the article West Indies. (*w*)

CHROMA, in Music, or Chromati, is the name by which M. Henfling has denominated the interval whose ratio is $\frac{24}{25}$, $=36\,\Sigma+f+3m$, being the Semitone *Minor*, which see. (ϱ)

CHROMATIC, in Music, is applied to such scales or passages, as proceed wholly, or in a larger degree than usual, by half notes, semi or hemitones; in which it is usually opposed to diatonic, or such scales or passages as proceed principally by whole notes or tones. The ancient Greeks had, or pretended to have, so many varieties of scales, or modes of dividing the tetrachord or minor fourth, into three degrees or intervals, that they have been classed into *genera*, of which the chromatic is one; which is distinguished by the two lower intervals being hemitones, and the other a third of some sort. Music of this genus is said to have had a tendency to produce or heighten expressions of grief or affliction, and its name to be derived from χρωμα, which is supposed to express a colour, and the blending or shading of such into each other; and so the chromatic semitones were supposed to blend or connect the tones, by the framers of these systems, as we are told. See Chromaticum, *Intensum, Molle, Sesquialterum*, and *Toniæum*. (ϱ)

CHROMATIC Diesis, in Music, (∂), is an interval so named and marked by Dr Callcott, which remains when the euharmonic diesis is taken from a medius semitone; or, when a major semitone is taken from the sum of a medius and minor semitone; and though noticed by no writer that we have read but Dr Callcott before Mr Liston, is rather an important interval, as the difference between ♭F and ✻E, and between ♭C and ✻B, in his euharmonic scale, or that adapted to perfect harmony. The ratio of the *chromatic diesis* is $\frac{16384}{16875}$; the component primes $\frac{2^{14}}{3^3\,5^4}$; its common logarithm is .9871761,5779; in the binary logarithms of Euler, or decimals of an octave, it is =.0426006; in those in which the major comma is the modulus, it is 2.376960; and where the schisma is the modulus or unit =26.165386; its value in the new notation is $26\,\Sigma+f+2m$; in the notation of elements of perfect tune, it is ƒ + Σ; in diatonic elements T + 2*t* — 3S; in chromatic elements 𝔖 + 𝒮 — S, as before observed; and in concordant, or tunable elements, it is 4 IIIds—3-4ths, whence, on such an instrument as Mr Liston's organ, it can be correctly tuned by perfect intervals only.

The following equations exhibit the value of the *chromatic diesis*, in terms of all the several intervals in the Table, Plate XXX. Vol. II. viz.

∂ = ƒ + Σ
= π + c
= ƒ€ + 2c
= đ + D
= 2đ + r
= ƒc + E

= 2𝔖 — S
= 2𝒮 — L
= 2π — ƒ€
= 2D — r
= 4III — 3-4ths

∂ = 𝔖 — E
= S — €
= ƒ — R
= P — ƒ
= L — 2€
= S — 2E

∂ = 26Σ + f + 2m
= 24Σ + 7f + 2d
= 16Σ + m + φ
= 12Σ + m + D
= 4Σ + f + 2c
= 11Σ + m + π
= 2Σ + χ + E

= 2Σ + 2c + r
= Σ + π + €
= Σ + χ + 2c

= 2f + 7đ — P
= f + 𝒮 — φ
= R + E — f

∂ = P + 𝒮 — S
= P + ƒ — S
= P + π — 𝔖
= P + ƒ€ — 𝒮
= P + 2𝒮 — T
= P + D — L
= S + 𝒮 — S
= S + Σ — ƒ
= T + t — 3S
= Σ + t — S
= 26d + 79f — 24m
= 27Σ + 3m — F
= 32Σ + 3m — R
= 2𝒮 + đ — P

∂ = T — E — S
= T — P — 2€
= €̄ — S — €
= S — c — 2€
= S — E — €
= 2S — P — 3€
= 2𝔖 — P — €
= 2π — 4Σ — f
= 2D — 2Σ — f
= S — 42Σ — 4m
= P — 32Σ — 3m
= 𝔖 — 21Σ — 2m
= L — 20Σ — 2m
= 𝒮 — 10Σ — m

(ϱ)

CHROMATIC Diesis, (least) of Chambers, Holder, &c. is an interval whose ratio is $\frac{24}{25}$, $=36\,\Sigma+f+3\,m$, and is the Semitone *Minor* 𝒮, which see. (ϱ)

CHROMATIC Dissonant Triad, in Music, or the *Superfluous Triad*, is a chord wherein two major or two minor thirds occur, as $\frac{\text{III}}{\text{III}}$ or $\frac{3}{3}$; the consonant triad consisting always of a major and minor third, as $\frac{\text{III}}{3}$, or $\frac{3}{\text{III}}$. (ϱ)

CHROMATIC Elements, in Music, or *Semitones o the Chromatic Douzeave Scale*, are the major, the medius, and minor semitones, S, 𝔖, and 𝒮, (see Plate XXX. Vol. II.) which were so denominated by Mr Farey in the *Philosophical Magazine*, vol. xxxix. p. 414, on finding, that upon Mr Liston's euharmonic, or perfect harmony organ, whatever changes are made by the use of the pedals for ♭s and ✻s among his 24 principal notes, these three intervals, and no others, (except the semitone maximum S between B✻ and C✻, with the 3d ✻ pedal,) are found between the adjacent notes of every new scale, in the progress of modulation. Thus in Mr Liston's *original scale*,

C C✻ D E♭ E F F✻ G G✻ A B♭ B C
𝔖 S S 𝒮 S 𝔖 S 𝒮 S S 𝔖 S
I II 3 III 4 V 6 VI 7 VII VIII

which are related to the key C, as in the lower line, by intervals major and minor, the differences or intermediary intervals are as expressed in the intermediate line and spaces; in which it may be observed, that if we begin at the 𝔖, between F and F✻, or above the 4th of the key, and proceed either upwards or downwards, the successive intervals and their order, are the same to S between B and C, or above the VIIth of the key; and in like manner, if we begin at the S last mentioned, or half tone below the key, and proceed both upwards and downwards, the order and magnitude of the intervals is the same. In the use of every new pedal, the order of these elements is changed, still however we have always 7 S + 3 𝔖 + 2 𝒮 = VIII, except with the use of Mr Liston's second and third sharp pedals, when 𝒮 below B✻ is substituted for S, and S + C above it for the 𝔖, that was before placed below C✻. (ϱ)

CHROMATIC French Horn. Since about the beginning of the 18th century, the attention of different musicians has been turned to the completing of the chromatic scale, or supplying the horn (and trumpet also) with additional notes, both for performing all the notes true in its own fundamental key, and for modulating into other keys. The late Mr Charles Clagget invented, and took out a patent a short time previous to 1790, and for a time made double horns and trumpets, one of which was tuned half a note lower than the other, and by means of a connected mouth-piece to these tubes, in which there was a valve moveable by the finger, the performer could sound either of these tubes at pleasure, and thus it was pretended, that a scale was produced, by sometimes using one tube and sometimes the other for different notes, and that the instrument was thus perfected for all the keys in which music is usually written. The following expressions for the notes of the horn or trumpet in ratios, to the whole length of the tube as unity, and, in our usual notation, will shew the fallacy of these pretensions, and prove useful on other occasions to the musical calculator, viz.

Notes.	Ratios.	Values. Σ	f	m	Intervals and Temperaments. I
C	$\frac{1}{2}$	612.	12	53	VIII
B	$\frac{8}{15}$	555.	11	48	VII
	$\frac{4}{7}$	494.05294	10	43	7th—13.94706 $\Sigma - m$
A	$\frac{8}{13}$	428.58107	9	37	VI—22.41893 $\Sigma - 2m$
	$\frac{16}{27}$	394.	8	34	6th—21. $\Sigma - 2m$
G	$\frac{2}{3}$	358.	7	31	V
	$\frac{16}{23}$	320.46026	6	28	5th + 9.46026 $\Sigma + m$
F	$\frac{8}{11}$	281.25171	5	24	4th + 27.25171 $\Sigma + 2m$
E	$\frac{4}{5}$	197.	4	17	III
	$\frac{16}{19}$	151.72902	3	13	3rd— 9.27098 $\Sigma - m$
D	$\frac{8}{9}$	104.	2	9	II
	$\frac{16}{17}$	53.53181	1	5	2d — 3.46819 Σ
C	$\frac{1}{1}$				I

In the column of ratios, the denominators shew the order in which these 12 notes arise by harder and harder blowing in the same tube; and the numerators, as multiples of 2, shew the successive octaves upwards, in which these notes are produced. In the last column, the temperaments or errors of the false notes of horns and trumpets are shown; thus the 4th of the key of C is 27¼ schismas and more *too sharp*, and the major sixth of the same key nearly 22½ schismas *too flat*, &c.; whence it is abundantly evident, that no *two* tubes can mutually supply or correct the false notes of the other, as Mr Clagget's invention assumes; nor will the same succeed any better, in fitting it for transposition or modulation into other keys, as will be easy for any one to try, by adding $612\Sigma + 12f + 53m$ to each of these notes in col. 3 for another octave above this, and then from these, when necessary, deducting the value of the note that is assumed as the new key, and comparing the difference with the perfect intervals in Plate XXX. Vol. II. whence the temperaments, or errors from the respective consonances, will appear for the octave above the new key, as they do in this table for that above C.

French-horns, bugle-horns, and trumpets, have of late been made by Mr Perceval, of St James's Street, with six side finger-holes, as in a flute, for supplying the notes that are false on the common instruments. It is evident, however, that though a considerable approach may be made on such polyphonian or chromatic horns, &c. by the adjustment of the places of the holes on the tube, to a perfect scale in C, or any other key, or even to any assumed tempered scale; yet it is well known, that modulation cannot be truly effected by help of any 12 notes whatever, except in that most inharmonious of all systems, the *equal temperament*, which no good ear could endure to hear in the few trials that have been made of it, much as it is talked and written about. The slide for lengthening or shortening the tube of the trumpet, which Mr Hyde has long used with such good effect in our best concerts, and the regulation of the notes on the horn which the Petrides effect, by thrusting their hand or a turned block of wood into the mouths of their horns, have not the effect of chromatic trumpets or horns, of which we have been speaking, where the scale consists of half-tones only; but by this management they become perfect instruments, (combined with the crooks that the latter use in different keys,) on which they can effect any of the small changes, for producing perfect harmony with the other notes of the piece, as on violins, voices, and Mr Liston's organ. (ϱ)

CHROMATIC INTERVAL, the greater, of Wood and Gregory, has a ratio of $\frac{15}{16}, = 57\Sigma + f + 5m$, and is the *Major* SEMITONE S; which see. (ϱ)

CHROMATIC *Interval*, the lesser, of Wood and Gregory, has a ratio of $\frac{24}{25}, = 36\Sigma + f + 3m$, and is the *Minor* SEMITONE S; which see. (ϱ)

CHROMATIC SEMITONE, greater, of Dr Callcott, has a ratio of $\frac{128}{135}, = 47\Sigma + f + 4m$, and is the SEMITONE *Medius*, S; which see. (ϱ)

CHROMATIC *Semitone*, lesser, of Dr Callcott, S. Rootsey, M. Tartinig, &c. has a ratio of $\frac{24}{25}, = 36\Sigma + f + 3m$, and is the SEMITONE *Minor S*. Dr Callcott in Art. 228, 1st Edit. of his "Grammar," has shown that these two chromatic semitones exist in the scale, according as they result from T or t, viz. T = S and t = S; but unfortunately, in Art. 163 to 175, 212 to 224, 315, &c. this essential distinction is not observed; but the term chromatic semitone is used synonymously with FLAT and SHARP. See those Articles in our work, and the *Philosophical Magazine*, Vol. xxxix, p. 375. (ϱ)

CHROMATICUM INTERSUM, in the Greek Music, was distinguished among their *genera*, according to Ptolemy, by a tetrachord, ascending according to the following numerical ratios, viz. $\frac{21}{22} \times \frac{11}{12} \times \frac{6}{7} = \frac{3}{4}$, which intervals, in the notation which we have adopted, (see Plate XXX. in Vol. II.) are as follows, viz.

$$\begin{aligned} \tfrac{6}{7} &= 136.052904\Sigma + 3f + 12m \\ \tfrac{11}{12} &= 76.748294\Sigma + 2f + 7m \\ \tfrac{21}{22} &= \underline{41.198802\Sigma \qquad + 3m} \\ \text{4th} &= 254.000000\Sigma + 5f + 22m \end{aligned}$$

(ϱ)

CHROMATICUM MOLLE, or soft chromatic, had, according to Euclid, a tetrachord ascending by a triental diesis, another such diesis, and a spiss or incomposite interval making up the fourth. This in our notation is as follows, viz.

$$\begin{aligned} & 184.766442\Sigma + 3f + 16m \\ \tfrac{1}{3}T &= 34.616779\Sigma + f + 3m \\ \tfrac{1}{3}T &= \underline{34.616779\Sigma + f + 3m} \\ \text{4th} &= 254.000000\Sigma + 5f + 22m \end{aligned}$$

The first of the above intervals was, it is said by Holder, accounted to be, "a tone and half and third part of a tone, that is, 1⅚ of a major tone, but which is $= 190.620711\Sigma + 4f + 16m$; differing 6.003931Σ from the above, or half the diaschisma, or ½d, what Galileo and Glarcanus call a *schisma*.

According to Aristoxenus, in this genus the tetrachord was divided into 30 equal parts, of which the tetrachord was thus composed, viz. 4+4+22=30, whence

$$\begin{aligned}\tfrac{22}{30}\text{ths or }\tfrac{11}{15}\times 4\text{th} &= 186.36750\Sigma+3f+16m\\ \tfrac{4}{30}\text{ths or }\tfrac{2}{15}\times 4\text{th} &= 33.81625\Sigma+f+3m\\ \tfrac{4}{30}\text{ths or }\tfrac{2}{15}\times 4\text{th} &= \underline{33.81625\Sigma+f+3m}\\ 4\text{th} &= 254.00000\Sigma+5f+22m\end{aligned}$$

According to Ptolemy, the numerical ratios in this genus were $\frac{27}{28}\times\frac{14}{15}\times\frac{5}{6}=\frac{3}{4}$, or the tetrachord, whence,

$$\begin{aligned}3d\text{ or }\tfrac{5}{6} &= 161.000000\Sigma+3f+14m\\ \tfrac{14}{15} &= 60.947096\Sigma+f+5m\\ \tfrac{27}{28} &= \underline{32.052904\Sigma+f+3m}\\ & 254.000000\Sigma+5f+22m\end{aligned}$$

Dr Pepusch is of opinion, in which he is followed by Mr Overend, that this genus was as follows, viz.

$$\begin{aligned}3d+E &= 182\Sigma+3f+16m\\ \mathcal{S} &= 36\Sigma+f+3m\\ \mathcal{S} &= \underline{36\Sigma+f+3m}\\ & 254\Sigma+5f+22m\end{aligned}$$

By having all these reduced to one rotation, as above, the curious reader of the authors above mentioned, can the readier compare these very different and discordant scales. (ϱ)

CHROMATICUM Sesquialterum, *Homiolium*, or *Sescuplum*, was a genus of the Greek music, which, according to Euclid, ascended by one and a half of his euharmonic diesis, or quarter of the major tone, another such an interval, and an incomposit, as follows, viz.

$$\begin{aligned} & 176.068934\Sigma+3f+16m\\ \tfrac{3}{8}T &= 38.965533\Sigma+f+3m\\ \tfrac{3}{8}T &= \underline{38.965533\Sigma+f+3m}\\ 4\text{th} &= 254.000000\Sigma+5f+22m\end{aligned}$$

The first of these intervals was, it is said by Holden, accounted to be 1½ of a major tone, or seven quarter tones, $=182.072865\Sigma+3f+16m$, differing 6.003931Σ, or just half of the diaschisma, or ½d, as before, in the molle.

According to Aristoxenus, the tetrachord, in this genus, was divided into 30 parts, and these distributed as follows, viz. $4\frac{1}{2}+4\frac{1}{2}+21=30$, whence

$$\begin{aligned}\tfrac{21}{30}\text{ths or }\tfrac{14}{20}\times 4\text{th} &= 177.870114\Sigma+3f+16m\\ \tfrac{4\frac{1}{2}}{30}\text{ths or }\tfrac{3}{20}\times 4\text{th} &= 38.064943\Sigma+f+3m\\ \tfrac{4\frac{1}{2}}{30}\text{ths or }\tfrac{3}{20}\times 4\text{th} &= \underline{38.064943\Sigma+f+3m}\\ 4\text{th} &= 254.000000\Sigma+5f+22m\end{aligned}$$

Dr Pepusch and Mr Overend state this genus as follows, viz.

$$\begin{aligned}3d &= 161\Sigma+3f+14m\\ \mathcal{S} &= 36\Sigma+f+3m\\ \mathfrak{S} &= \underline{57\Sigma+f+5m}\\ 4\text{th} &= 254\Sigma+5f+22m\end{aligned}$$

This is also the chromatic in Didymus's genera. (ϱ)

CHROMATICUM Toniæum, or *Tonicum*, was a genus, according to Euclid, where the tetrachord rose by hemitone, hemitone, and trihemitone as follows, viz.

$$\begin{aligned} & 149.992138\Sigma+3f+14m\\ \tfrac{1}{2}T &= 52.003931\Sigma+f+4m\\ \tfrac{1}{2}T &= \underline{52.003931\Sigma+f+4m}\\ 4\text{th} &= 254.000000\Sigma+5f+22m\end{aligned}$$

The first of the above intervals, is the comma-deficient minor third, $=150\Sigma+3f+13m$, (though differently expressed, in order to throw the decimal parts, all on the schisma,) and is the trihemitone of Euclid.

According to Aristoxenus, this tetrachord is thus divided, viz. 6+6+18=30, whence

$$\begin{aligned}\tfrac{18}{30}\text{ths or }\tfrac{3}{5}\times 4\text{th} &= 152.39370\Sigma+3f+14m\\ \tfrac{6}{30}\text{ths or }\tfrac{1}{5}\times 4\text{th} &= 50.80315\Sigma+f+4m\\ \tfrac{6}{30}\text{ths or }\tfrac{1}{5}\times 4\text{th} &= \underline{50.80315\Sigma+f+4m}\\ 4\text{th} &= 254.00000\Sigma+5f+22m\end{aligned}$$

Dr Pepusch and Mr Overend state this genus as follows, viz.

$$\begin{aligned}T+\mathcal{S} &= 140\Sigma+3f+12m\\ \mathfrak{S} &= 57\Sigma+f+5m\\ \mathfrak{S} &= \underline{57\Sigma+f+5m}\\ 4\text{th} &= 254\Sigma+5f\times 22m\end{aligned}$$

The genera that are ascribed to Archytas, have a chromatic different from any of the above, viz.

$$\begin{aligned}\tfrac{27}{32} &= 150.000000\Sigma+3f+13m\\ \tfrac{224}{243} &= 71.947096\Sigma+f+6m\\ \tfrac{27}{28} &= \underline{32.052904\Sigma+f+3m}\\ 4\text{th} &= 254.000000\Sigma+5t+22m\end{aligned}$$

Aristides ascribes another chromatic to the ancient Pythagoreans, having the same comma-deficient minor third as above, viz.

$$\begin{aligned}\tfrac{27}{32} &= 150.00000\Sigma+3f+13m\\ \tfrac{17}{18} &= 50.46819\Sigma+f+4m\\ \tfrac{16}{17} &= \underline{53.53181\Sigma+f+5m}\\ 4\text{th} &= 254.00000\Sigma+5f+22m\end{aligned}$$

A genus ascribed to Eutosthenes, also differs from any of the above, as follows, viz.

$$\begin{aligned}\tfrac{5}{6} &= 161.000000\Sigma+3f+14m\\ \tfrac{18}{19} &= 47.729018\Sigma+f+4m\\ \tfrac{19}{20} &= \underline{45.270982\Sigma+f+4m}\\ & 254.000000\Sigma+5f+22m\end{aligned}$$

(ϱ)

CHRONOLOGY.

Definition.

CHRONOLOGY, from *χρονος time*, and *λογος doctrine*, is that science which treats of the natural and artificial divisions of time, and refers to the points which it thus marks out, the various events recorded in history, &c.

Division.

In order to convey to our readers as full and distinct an account of this useful subject as our limits will permit, we shall divide it into the following Chapters: I. MATHEMATICAL CHRONOLOGY; II. HISTORICAL CHRONOLOGY; III. COMPARATIVE CHRONOLOGY; and, IV. TABULAR CHRONOLOGY.

CHAP. I.

Mathematical Chronology.

Mathematical chronology.

MATHEMATICAL chronology treats of the division of time by days, months, years, and cycles, and of the application of these divisions to the purposes of civil life.

SECT. I. *On the Day.*

On the day.

A day is that portion of time which elapses while the earth performs a complete revolution about its axis; and its length is measured by observing the precise instant when the centre of a star passes the meridian on two consecutive days. A day thus measured is called the *sidereal day*, and consists of 23 hours, $56'\,3''.4$. A *solar* or *natural* day, is that portion of time which elapses between the arrival of the sun at the meridian on two consecutive days. The mean length of the solar day is 24 hours; but, owing to the inclination of the earth's axis to the ecliptic, and the unequal motion of the earth in its orbit, the solar days are of unequal length, sometimes exceeding, and sometimes falling short of 24 hours. The hour hand of a well-regulated clock performs two complete revolutions on the dial plate in the course of a mean solar day, and twice 365 or 720 revolutions in the course of a year; whereas the shadow of the stile or gnomon of a sun dial, sometimes performs more and sometimes less than one revolution during a mean solar day, but always completes 365 revolutions in the course of one year. The difference between the mean solar time, as shewn by a well-regulated clock, and the apparent time, as shewn by a sun dial, is called the equation of time, or the equation of natural days, and has been fully explained in the article ASTRONOMY, Vol. II. Pp. 652, 797.

Although the inhabitants of every country have agreed in adopting the mean solar day as the unit of their scale for measuring time, yet they have differed from each other in fixing its commencement. The following Table will shew distinctly the practice of various ancient and modern nations.

Table of the commencement of the day among various nations.

Table shewing the Times at which different Nations have begun or begin the Civil Day.

Ancient Babylonians	at sunrise.
Ancient Persians	ditto.
Ancient Syrians	ditto.
Ancient Jews	ditto.
Almost all Eastern nations	ditto.
Inhabitants of Majorca, Minorca, and Ivica	ditto.
The Greeks and the inhabitants of the islands of the Archipelago	ditto.
Athenians and the inhabitants of Attica	at sunset.
The Marcomanni	ditto.
Austrians	ditto.
Turks	ditto.
Bohemians	ditto.
Silesians	ditto.
Italians	ditto.
Ancient Umbrians	at mid-day.
Ancient and modern Arabians	ditto.
Astronomers of all nations	ditto.
Ancient Egyptians	midnight.
English	ditto.
French	ditto.
Germans	ditto.
Dutch	ditto.
Russians	ditto.
Spaniards	ditto.
Swiss	ditto.
Portuguese	ditto.
Danes	ditto.
Swedes, Laplanders, Americans, and Araucanians	ditto.
Modern Chinese	ditto.

Subdivision of the day.

The subdivision of the day into particular parts has likewise been different among different nations. The Chaldeans, Syrians, Persians, Indians, Jews and Romans, divided both the day and night into four parts. The Greeks divided the natural day into 12 hours in imitation of the Babylonians, and this practice was afterwards adopted by the Romans. Among almost all modern nations, the day is divided into 24 hours, reckoned twice from 1 to 12, except among the Italians, Bohemians, and Poles, who reckon them from 1 to 24. The Araucanians divide the natural day into 12 parts, each of which has a particular name. The Turks follow the practice of the Jews; and the Chinese divide the mean solar day into 12 hours, each of which is of course equal to two of ours. In the decimal system adopted by the French, the day is divided into 10 hours.

The various methods which have been employed for measuring the subdivisions of the mean solar day by *Clepsydræ, Dials, Clocks, and Watches*, will be discussed under the articles DIALLING, HOROLOGY, HYDRODYNAMICS, and TIMEKEEPER.

SECT. II. *On the Month.*

On the month.

The next convenient division of time which is marked out by the revolutions of the heavenly bodies is the month. The *astronomical* month is the time in which the moon performs a complete revolution round the heavens, and is either *periodical* or *synodical*. The *periodical* month is the time in which the moon moves from one point of the heavens to the same point again, and is equal to $27^d\,7^h\,43'\,4''.7$; and the *synodical* month, or *lunation* as it is sometimes called, is that portion of time which elapses between two successive new moons, or between two successive conjunctions of the moon with the sun, and is equal to $29^d\,12^h\,44'\,3''\,11'''$. The *solar* month is that portion of time in which the sun moves through one sign of the ecliptic, and is equal at an average to $30^d\,10^h\,29'\,5''$. The *civil* month, which is formed for the purposes of civil life, is one, which consists of a certain number of whole days, and approaches as nearly as possible to the astronomical or to the solar month.

When the civil month approaches to the lunar month, it is called the civil lunar month, and generally contains 29 and 30 days alternately, with some corrections. This kind of month was used by the Jews, Greeks, and Romans, till the time of Julius Cæsar, who introduced the civil solar month, consisting of 30 and 31 days alternately.

In the following Tables, we have shewn the method of dividing the year into months, adopted by the Egyptians, Jews, Greeks, Romans, Arabs and Turks, and the French.

Egyptian months.

No. I. *Egyptian Months.*

No.	Names.	Signification.	Corresponding Months in our Calendar.		Number of days in each.
1	Thoth	Mercury	August	29	30
2	Paophi	Serpent	September	28	30
3	Athir	Venus	October	28	30
4	Chojac	Verdure	November	27	30
5	Tybi	Good month	December	27	30
6	Mechir	Venus	January	26	30
7	Phamenoth	Good moon	February	25	30
8	Parmuthi	Corn thrashed	March	27	30
9	Pachon	Hercules	April	26	30
10	Payni	The protector	May	26	30
11	Epiphi	Osiris	June	25	30
12	Mesori	Last month	July	25	30
	Epagomenæ or days added				5
	Number of days in the year				365

Jewish months.

No. II. *The Jewish Months.*

No.	Names.	Signification.	Corresponding Months in our calendar.	Number of days in each.
1	Tisri		Aug.—Sept.	30
2	Marchesvan	Great Ram	Sept.—Oct.	29
3	Casleau	Stormy weath.	Oct.—Nov.	30
4	Tebeth	Hope	Nov.—Dec.	29
5	Shebat	Repose	Dec.—Jan.	30
6	Adar	Purifying fire	Jan.—Feb.	29
7	Nisan or Abib	Standard	Feb.—March	30
8	Jiar	Wat. meadow	March—April	29
9	Sivan	Anim. in past.	April—May	30
10	Tamuz	The sun	May—June	29
11	Ab	Fruit	June—July	30
12	Elul	Vine press	July—August	29
	Number of days in the year			354

In the *Embolimic* year after the month *Adar* the Jews added a month of 30 days, called *Ve-Adar.*

Greek months.

No. III. *The Ancient Grecian Months.*

No.	Names.	Signification.	Corresponding Months in our Calendar.	Number of days.
1	Hecatombæon	The names of the Greek months are derived from the names of the festivals which were celebrated in each.	June—July	30
2	Metagitnion		July—Aug.	29
3	Boedromion		Aug.—Sept.	30
4	Pyanepsion		Sept.—Oct.	29
5	Maimacterion		Oct.—Nov.	30
6	Posideon		Nov.—Dec.	29
7	Gamelion		Dec.—Jan.	30
8	Anthesterion		Jan.—Feb.	29
9	Elaphebolion		Feb.—March	30
10	Municheon		March—April	29
11	Thargelion		April—May	30
12	Schirrophorion		May—June	29
	Number of days in the year			354

Roman months.

No. IV. *Roman Months before the reformation of the Calendar.*

Roman names.	Number of days.	English names.
Januarius	29	January
Februarius	28	February
Martius	31	March
Aprilis	29	April
Maius	31	May
Junius	29	June
Quintilis, afterwards Julius	31	July
Sextilis, afterwards Augustus	at first 29 afterwards 31	August
September	29	September
October	31	October
November	29	November
December	29	December

Arabic and Turkish months.

No. V. *Arabic and Turkish Months.*

No.	Names.	Signification.	Corresponding Months in our Calendar.		Number of days in each.
1	Muharram	Sacred month	July	16	30
2	Saphar	Month of study	August	15	29
3	Rabia I.	Honoured month	September	13	30
4	Rabia II.	Id.	October	13	29
5	Jomada I.	Month of prayer	November	11	30
6	Jomada II.	Id.	December	11	29
7	Rajab		January	9	30
8	Shasban	Month of hope	February	8	29
9	Ramadam	Month of heat	March	9	30
10	Shawal		April	8	29
11	Dulhaadah	Month of repose	May	7	30
12	Dulheggia	Month of ceremonies	June	5	29
	Number of days in the year				354

The Arabians add 11 days at the end of every year to preserve a coincidence between the months and the seasons.

French months.

No. VI. *French Months.*

Names.	Signification.	Corresponding Months in our Calendar.		Number of days in each.
Vendemiare	Vintage month	September	23	30
Brumaire	Foggy month	October	23	30
Frimaire	Sleety month	November	22	30
Nivose	Snowy month	December	23	30
Pluviose	Rainy month	January	21	30
Ventose	Windy month	February	20	30
Germinal	Budding month	March	22	30
Floreal	Flowery month	April	21	30
Prairial	Meadow month	May	21	30
Messidor	Harvest month	June	20	30
Thermidor	Hot month	July	20	30
Fructidor	Fruit month	August	19	30
Number of days				360

As the French months consist of 30 days each, making in all 360 days, the remaining 5 days are called *complementary days,* and *sans culottides,* the first of which is the 18th September, the second the 19th, the third the 20th, the fourth the 21st, and the fifth the 22d of September, which terminates the French year.

Each month is divided into three decades, consisting of 10 days each, which are called *primidi, duodi, tridi, quartidi, quintidi, sextidi, septidi, octodi, nonodi,* and *decadi.* For an account of the French year, and their method of intercalation, see Section III. *On the Year.*

Greek months. As the Grecian months consisted of 30 and 29 days alternately, the former were called πληρεις, *full*, and δεκαφθινοι, as ending on the 10th day; while the latter received the name of κοιλοι, or *hollow*, and εναφθινοι, or terminating on the 9th day. They divided each month into three decades of days, (τρια δεκημερα,) which received the following names:

First decade was called μηνος αρχομενου, or ισταμενου.
Second, ... μηνος μεσουντος.
Third, ... μηνος φθινοντος, απιοντος, παυομενου,
or ληγοντος.

Hence the days of the month were reckoned in the following manner:

1st day of 1st decade, was called νουμηνια, as falling on the day of new moon, or πρωτη αρχομενου, or ισταμενου.
2d day, ... δευτερα ισταμενου.
3d day, ... τριτη ισταμενου.
And so on with the rest down to the 10th, or δεκατη ισταμενου.
1st day of 2d decade, which was the 11th of the month, was called . . . . πρωτη μεσουντος, or πρωτη επι δεκα.
2d day, ... δευτερα μεσουντος, or επι δεκα.
And so on with the rest to the εικας, or 20th.
1st day of the 3d decade, was called πρωτη επ᾽ εικαδι.
2d day, ... δευτερα επ᾽ εικαδι
And so on with the rest.

Sometimes the Greeks inverted the numbers, and called the first day φθινοντος, or απιοντος δεκατη, the second day φθινοντος ενατη, and so on to the last day of the month, which had the name of Δημητριας, from Demetrius Poliorcetes. This day was also called τριακας, the thirtieth; and, in the laws of Solon, it is named ενη και νεα, *the old and new*, as part of it belonged to the old moon, and part of it to the new one, which happened upon that day.

Roman months. Before the reformation of the Roman calendar by Julius Cæsar, the Romans divided their months into kalends, nones, and ides. The name kalends, derived from the old word *calo*, to call, was given to the first day of every month, because, before the fasts were published, the pontiff assembled the people in the capitol, and proclaimed with a loud voice the number of the kalends, or the days on which the nones should happen. The formula *Calo Juno Novella*, was repeated as often as there were days in the kalends. The term *nones*, applied to the 5th day of those months that have 29 days, and to the 7th of those that have 31 days, is derived from *nonus*, the ninth, and was used, because they always happened 9 days before the ides. The *ides*, which fell on the 13th of those months that have 29 days, and the 15th of those that have 31 days, is derived from *iduare*, to divide, and was applied to the third division of the Roman months, because it divided the month nearly into two parts.

Hence there were in months

Of 29 days,	Of 30 days,	Of 31 days,
1 day of kalends,	1 day of kalends,	1 day of kalends,
4 . . . . . of nones,	4 . . . . . . of nones,	6 . . . . . . of nones,
8 . . . . . of ides,	8 . . . . . . of ides,	8 . . . . . . of ides,
16 called the kalends of the following month,	17 called the kalends of the following month,	16 called the kalends of the following month,
29 days.	30 days.	31 days.

The method of naming the days of each month will be apparent from the following Table, which is for January, a month of 29 days.

Roman Calendar.

Number of Days in the Month.	Names given to the Days of the Month by the Romans.	General Division of the Month.
1	KALENDUS JANUARII.	One day of Kalends.
2	IV. Nonas.	4 days of Nones.
3	III. Nonas.

26	V. Kal. Feb.	
27	IV. Kal. Feb.	
28	III. Kal. Feb.	
29	Pridie Kal. Februarii.	

At the reformation of the calendar by Julius Cæsar, of which we shall soon give a full account, two days were added to the months of January, August, and December, and one to April, June, September, and November. The stile of the calendar, engraved on a square piece of marble, was then exposed every month in the principal public places, for the information of the people. The following example for January may be interesting to some of our readers.

MENSIS

DIIS
PENATIBUS.

Weeks. The subdivision of the month into weeks is very ancient, and has been adopted by almost all nations, excepting the ancient Greeks, the inhabitants of the north of China, the Persians, and the Mexicans. It originated with the ancient Chaldeans, who gave the name of one of the seven planets to each hour of the day, and designated each day by the name of that planet which corresponded with the first hour of the day. In consequence of this arrangement, it necessarily happened, that each day of the week was marked by the name of the planet which it now bears. In order to understand this, the order of the planets must be given upon the Ptolemaic system. Thus,

1. Saturn.
2. Jupiter.
3. Mars.
4. Sun.
5. Venus.
6. Mercury.
7. Moon.

As the day was divided into 24 hours, and as every hour was called after one of the planets in their order, the planets would be numbered *three* times in the first day, and the three first planets four times. Thus,

Origin of the names given to the days of the week.

Therefore the fourth planet, or the *Sun*, will belong to the first hour of the second day, and will consequently be the name of that day. . . . . $7+7+7+3$

During the second day, we have . . . $4+7+7+6$

From which it follows that the seventh planet, or the *Moon*, will commence the third day.

During the third day, we have . . $1+7+7+7+2$

Hence the 3d planet, or *Mars*, will mark the first hour of the fourth day.

During the fourth day, we have . . . $5+7+7+5$

Hence the 6th planet, or *Mercury*, will designate the 1st hour of the 5th day.

During the fifth day, we have . . $2+7+7+7+1$

Hence the 2d planet, or *Jupiter*, will mark the first hour of the 6th day.

During the 6th day we have . . . . $6+7+7+4$

Hence the 5th planet, or *Venus*, will mark the 1st hour of the 7th day.

During the seventh day, we have . . . $3+7+7+7$

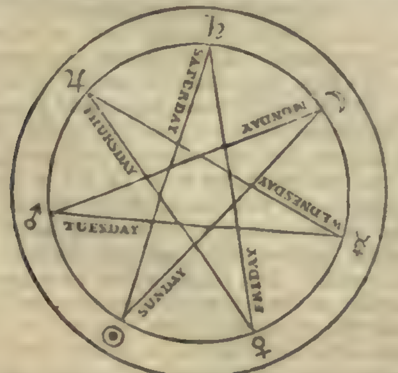
Consequently the first planet, or *Saturn*, will mark the 1st hour of the eighth day, and so on with the rest, the same planets marking the same days of every weekly period.

Hence we have the following arrangement:

1st day of the week Saturday, or the day of Saturn.
2d . . . . Sunday, ... day of the Sun.
3d . . . . Monday, ... day of the Moon.
4th . . . . Tuesday, ... day of Mars.
5th . . . . Wednesday, ... day of Mercury.
6th . . . . Thursday, ... day of Jupiter.
7th . . . . Friday, ... day of Venus.

This order of the days, first adopted by the Chaldeans, was preserved by the Mosaic law. The Christians, however, began their week on Sunday, and the Mahometans on Friday.

The denomination of the days of the week has also been explained by the following diagram, in which the seven planets are placed in their order round the circle.



At the mark ♄, or Saturday, the line directs us to ☉, or Sunday, which again directs us to ☽, or Monday, then to ♂, or Tuesday, from which we are led to ☿, or Wednesday, and from this to ♃, or Thursday, which conducts us to ♀, or Friday.

SECT. III. *On the Year and the Reformation of the Calendar.*

The next and most important chronological period indicated by the celestial motions is the year.

Solar year.

The *solar* or *tropical* year, is that period which corresponds to the sun's revolution in the ecliptic from any equinox or solstice to the same again, and consists of 365 days $5^h\ 48'\ 54''$.

Sidereal year.

The *sidereal year*, is that portion of time which corresponds to the revolution of the sun from any fixed star to the same star again, and is equal to 365 days $6^h\ 9'\ 15''$, or $20'\ 21''$ shorter than the solar year.

Lunar year.

The *lunar year* is equal to twelve revolutions of the moon from the sun to the sun again, or from one conjunction with the sun to the next conjunction. It contains 354 days $8^h\ 48'\ 36''$, and is 10 days $21^h\ 0'\ 18''$ shorter than the solar year.

Civil year.

The *civil year* is that which is used for the purposes of civil life.

In the earliest periods of society, the most barbarous nations could not fail to observe a regular return of the seasons; and the necessity of providing against the inclemency of winter, or the burning heat of the summer season, must have compelled them to ascertain, in a rude manner, the length of the year. The period in which the seasons returned would probably be measured at first by the motions of the moon, and be reckoned equivalent to 12 of her monthly revolutions. Hence a year of 12 lunations would be formed, each of which consisted of 30 days, forming the lunisolar year of 360 days. This form of the year was adopted by the Chaldeans, Egyptians, and Indians, and was in use among almost all the nations of antiquity. As the true solar year, however, of 365 days $5^h\ 48'\ 54''$ exceeded the lunisolar year by about 5¼ days, the seasons would rapidly deviate from the months to which they at first corresponded, and in the short space of 34 years, the winter would happen in those months which formerly corresponded with the summer season. This enormous aberration was observed by almost all nations, and was corrected by the addition of a few intercalary days at certain intervals. By this means, independent of astronomical observation, the length of the solar year would soon be found to consist of 365 days. The Egyptians were very early acquainted with the year of 365 days. The Theban priests ascribed the invention of it to Mercury or Thoth; and it seems to have been known in the 12th or 13th century before the Christian æra.

Canicular year.

As the inundation of the Nile was annually announced by the heliacal rising of Sirius, which was made to correspond with the beginning of the year, it was soon discovered that the heliacal rising of this star advanced nearly one day in four years, and that in the space of 1461 years it would complete a whole revolution till it again happened on the day originally fixed for the commencement of the year. This period, which was equal to 1460 Julian years, was called the Great Egyptian or Canicular Year.

Reformation of the calendar.

It is impossible to ascertain the time when the true solar year was discovered. The Theban priests lay claim to the discovery, and the knowledge of it is said to have been introduced into Greece by Plato and Eudoxus, who obtained it as a secret from the Egyptians; but at whatever time this knowledge was obtained, it does not appear to have been employed for the purpose of adjusting the civil with the solar year, till the time of Numa Pompilius.

Romulus divided the year into 10 months or 304 days, March, May, Quintilis, and October having 31 days, and the rest 30: He made it commence on the first of March; but there is no evidence for believing that any method was adopted for reconciling this singular calendar with the return of the seasons.

Changes made upon the calendar by Numa.

With the view of making a complete lunar year of 354 days, Numa added 50 days to the 304 days or 10 months of Romulus. He borrowed one day from each of the months of 30 days, and out of these 56 supernumerary days he formed the months of January and February. In order to make the number of days in the year 355 a lucky number, he added one day to January, and transferred the beginning of the year to the first of January, February being placed at the end of the year. As the year of 355 days is 11¼ shorter than the solar year, the excess of the latter amounted in 8 years to 90, and accordingly this number of days was intercalated every 8 years. They were formed into four months of 22 and 23 days alternately, and one of these months was intercalated every two years, thus

In the first 2 years, 22 days were added to the second year.
In the next 2 years, 23 . . . . fourth year.
2 years, 22 . . . . sixth year.
2 years, 23 . . . . eighth year.
$\overline{90}$

But since the excess of the solar year above 365 days is here assumed at 6 hours instead of $5^h\ 48'\ 45''$, the intercalations were too great by 8 days $1^h\ 27'\ 56''$. To remedy this defect, 66 days instead of 90 were to be added in every third octennial period, or 3 months of 22 days each. This addition was still too great by $4^h\ 28'\ 20''$, but the calendar thus rectified was sufficiently correct for all the purposes of civil life.

Reformation of the calendar by Julius Cæsar.

From the negligence of the pontiffs, however, to whom the duty of intercalation was confided, the supernumerary months were not properly applied; and in the time of Julius Cæsar the civil had receded from the solar year by no less than 90 days. With the assistance and advice of Sosigenes, Julius Cæsar undertook, B. C. 46, the formation of a new calendar. In order to include the 90 days which had been lost, he formed a year of 355+90=445 days or 15 months; and this year, which was called the year of confusion, terminated on the day preceding the first of January B. C. 46, in which the Julian year commenced. The 10 days which the year of Numa fell short of the solar year, were included by adding one day to January, August, and December, and one to April, June, September, and November, and the year was thus made to consist of 365 days. The excess of six hours, which amounted to one day in four years, was taken into account by making every fourth year consist of 366 days. This intercalary day was added to the 23d of February, that is, the 24th day, or the 6th of the calends of March, was twice counted. Hence the year of 366 days was called *Bissextile* by the Romans; and it has very improperly received the name of *Leap year* in this country, an appellation which might have been more appropriate had it consisted of 364 days.

Reformation of the calendar by Pope Gregory.

This correction of the calendar, though extremely simple and ingenious, was still imperfect, as it was founded on the supposition that the solar year consisted of 365 days 6 hours, instead of 365 days $5^h\ 48'\ 45\frac{1}{2}''$. The difference between the one employed by Julius Cæsar, and the true solar year was therefore $11'\ 14\frac{1}{2}''$, which amounted to a whole day in 130 years. This imperfecion in the Julian calendar was first noticed by the venerable Bede in 730; and at the Council of Nice, which met in 325, the vernal equinox, which happened on the 25th of March, in the time of Julius Cæsar, had receded to the 21st of March, where it was fixed by the council. The necessity of some change in the calendar was now obvious, and attempts were made at different times to accomplish this desirable object; but it was not till near the close of the 16th century that a complete reformation was effected by Pope Gregory XIII. The most learned astronomers and mathematicians of the age were invited to Rome to consider this important subject, and after it had undergone a discussion of ten years, the plan proposed by two brothers, Aloisius and Antoninus Lilius, from Verona, was ultimately preferred. Copies of this plan were sent to all Catholic states, academies, &c. in A. D. 1577, and in March 1582, a brief was published, abrogating the ancient calendar, and substituting in its room the new *Gregorian Calendar*.

In the year 1582, the vernal equinox had receded ten days since the Council of Nice, and happened on the 11th instead of the 21st of March. It was therefore decreed, that the vernal equinox should be brought back to the 21st of March as in the year 325, and that for this purpose ten days should be taken from the month of October 1582. In order to avoid any future deviation of the civil from the solar year, it was determined that instead of every 100th or centurial year being a leap year, every 400th year only should be a leap year. By this means the excess of the civil Julian year of 365 days 6 hours above the tropical or solar year of 365 days $5^h\ 48'\ 45\frac{1}{2}''$ was taken into account, and in the course of 5000 years the error of this method of intercalation does not exceed one day and a half to be suppressed.

The calendar thus reformed was immediately introduced into all Catholic countries, viz. Spain, Portugal, and part of Italy; but it was not received in France till December, when the 10th was reckoned the 20th of the month. The German Catholic states adopted the new calendar in 1583; but the Protestants, actuated by a mean and unworthy jealousy, declined to receive a measure which originated among the Catholics. Time, and the progress of liberal sentiment, however, gradually removed their objections, and in the year 1700 the Protestant states in Germany adopted the Gregorian calendar. In 1752, an act of parliament was passed in this country, by which the 3d of September was reckoned the 14th; and in 1753 the new style was introduced into Denmark and Sweden. The Russians, however, still reckon by the old style; but from the important events which are now passing in Europe, it is probable that this great empire will conform to the usages of all civilized nations.

French calendar.

The zeal for innovation which accompanied the French revolution, induced them to change their calendar along with their government. It was decreed by the convention, that the vulgar æra should be abolished in all civil concerns; that the new French æra should be reckoned from the foundation of the republic Sept. 22. 1792 of the vulgar æra, on the day of the true autumnal equinox, when the sun entered Libra at $9^h\ 18'\ 30''$ in the morning, according to the meridian of Paris; that each year should begin at the midnight of the day on which the true autumnal equinox falls; and that the first year of the French republic had begun on the midnight of the 22d September, and terminated on the midnight between the 21st and 22d September 1793. In order to effect a correspondence between the seasons and the civil year, it was decreed that the 4th year of the republic should be the first *sextile*, or leap year; that a sixth complementary day should be added to it; and that it should terminate the first *franciade*; that the sextile, or leap year, should take place every 4 years, and should mark the close of each franciade; that the 1st, 2d, and 3d centurial years, viz. 100, 200, and 300 of the republic, should be common, and that the 4th, viz. 400, should be sextile; and that this should be the case every 4 centuries till the 40th, which should terminate with a common year.

Table of the times at which different nations began the year.

The following Table shews the various Times at which different Nations have begun the Civil Year.

Names of the Nations.	Time when the Year begins.
Egyptians, . . .	Autumnal equinox.
Chaldeans, . . .	Id.
Persians, ...	Id.
Syrians, ...	Id.
Phenicians, . . .	Id.
Carthaginians,	Id.
Jews, ...	Id. for their civil year.
——	Vernal equinox for their ecclesiastical year.
Greeks, ...	Winter solstice before the time of Meton.
——	Summer solstice after Meton.
——	Vernal equinox in the time of Romulus.
Romans, ...	Winter solstice in the time of Numa Pompilius.
Scandinavians,	Winter solstice.
Ancient and modern Chinese,	With the first new moon which appears after the sun is in the 1st of Aquarius.
English, ...	Winter solstice.
French, ...	At St Martin's. This was used by the Monks at a very early period.
——	On the 1st May under the 1st race of kings.
——	Winter solstice under the 2d race of kings.
——	Vernal equinox, under the 3d race of kings.
——	Winter solstice, by an ordonnance of Charles IX. 1564.
——	Autumnal equinox, since the establishment of the republican æra.
Spaniards, . . .	Winter solstice.
Portuguese, . .	Do.
Dutch, ...	Do.
Germans, . . .	Do.
Siamese, ...	Do.
Peruvians, . . .	Do.
Americans, . .	Do.
Mexicans, . . .	Vernal equinox.
Venetians, Florentines, Pisans, and inhabitants of Treves, . .	Vernal equinox.
American Indians,	First new moon of the vernal equinox.
Turks and Arabs,	16th of July.
Japanese, . . .	New moon nearest to the winter solstice.
Araucanians, . .	22d December at the winter solstice.

SECT. IV. *On Cycles.*

On cycles.

A *cycle*, derived from the Greek word κυκλος, a *circle*, is a circulating period of time, at the expiration of which certain celestial phenomena return in the same order.

The *Metonic cycle*, or the lunar cycle of Meton, is a period of 19 solar years, or 6940 days, in which the conjunctions, and oppositions, and other aspects of the moon, are within an hour of being the same as they were on the same days of the month nineteen years before. This cycle was adopted on the 16th of July, B.C. 433. As the scheme of the festivals was inscribed by the Greeks on a marble pillar in letters of gold, the current year of this cycle was called the Golden Number. The Metonic cycle, though remarkably simple, is nevertheless far from being exact. A period of 6940 days exceeds 19 solar years by 9½ hours, and 235 lunations by 7½ hours, and these deviations would, in the course of 4 cycles, or 76 years, amount to more than a day. In consequence of this defect, Calippus, who lived about a century after Meton, proposed a new cycle of 27,759 days, which is nearly equal to 76 solar years and 940 lunations. This cycle, which supposes the tropical year to be 365¼ days, anticipates the full moons only $5^{h}\ 53'$ in 76 years.

In order to find the golden number, or the current year of the lunar cycle, we must consider that the year of our Saviour's birth, according to the vulgar æra, was the first year of the lunar cycle; and, therefore, if we add one to the year of Christ, for which the golden number is required, and divide the sum by 19, the quotient will be the number of cycles which have elapsed since the birth of Christ, and the remainder will be the golden number or the current year of the cycle. If there is no remainder, the cycle is 19.

The following Table shews the golden number for 4000 years after the Christian æra. By entering the Table on the left hand with the even number of years in the given year, and at the head of the Table with the years less than 100, the golden number will be found at the angle where the columns meet. Thus, if the golden number is required for the year 1820, we look for 1800 at the left side, and for 20 at the top, and at the angle we find 16, which is the golden number for that year.

Table I. *Shewing the Golden Number, or current year of the Lunar Cycle, which is the same both in the Old and New Stile, from the Birth of Christ to A. D. 4000.*

Hundreds of Years.			Years less than an Hundred.

1800	3700	—	15	16	17	18	19	1	2	3	4	5	6	7	8	9	10	11	12	13	14

The following Table is useful for finding the time of new moon from the golden number. It is suited to the new stile, and principally to the second year after leap year, and will serve till A. D. 1900. In order, therefore, to find the day of new moon for any month of a given year before A. D. 1900, we have only to look for the golden number under the given month, and opposite to it, on the left hand column, will be found the time of new moon. Thus, if we require the time of new moon in June 1820, we find, from the preceding Table, that the golden number for that year is 16, and opposite to this number, in the column for June, will be found the 10th day of the month.

Table II. *Shewing the time of New Moon from the Golden Number, till the year A. D. 1900.*

Solar cycle.

The *solar cycle* is a period of 28 years, at the end of which the days of the week correspond to the same days of the month.

Dominical letter.

The first seven letters of the alphabet A, B, C, D, E, F, G, have been employed by chronologers to mark the several days of the week, the first letter standing for the first of January and so on; and since one of these letters must necessarily stand opposite to Sunday, it is called the *dominical letter,* or Sunday letter, and is printed in a capital form, the other six letters, which designate the other six days of the week, being printed in small characters. Then, since a Julian year of 365 days contains 52 weeks and one day, it is obvious that the year must begin and end on the same day of the week, and consequently the next year must commence on the day following. Had there been only 52 weeks in the common year, without any days remaining, the year would have constantly begun on the same day of the week. When January, therefore, begins on Sunday, the dominical letter for that year is A, and since the next year must begin on Monday, Sunday will be the 7th day, to which the letter G is annexed, which will therefore be the dominical letter for that year. The third year will begin on Tuesday, and as Sunday falls on the sixth day, F will be the dominical letter. Hence it follows that the dominical letters will succeed each other in a retrograde order, viz. G, F, E, D, C, B, A, and if there was no leap year, the same days of the week would, in the course of *seven* years, return to the same days of the month. But since leap year contains 52 weeks, and two days over, any leap year beginning on Sunday, will end on Monday, and the following year will begin on Tuesday, the first Sunday of which must fall on the sixth of January, to which the dominical letter F corresponds, and not G as in common years. As the leap year returns every fourth year, the regular succession of the dominical letter is interrupted, and does not return to its former state till after 7 × 4, or 28 years; when the same days of the week will correspond with the same days of the month as formerly.

The following Tables contain the dominical letters both for the old and new stile, and will be understood from the annexed example.

Example. *Let it be required to find the dominical letter for the year* 150 *before Christ.* Subtract one from the given year, which leaves 149, and it will be found from entering Table IV. with the 100 years at the head, and the 49 at the side, that A is the dominical letter required.

Use of Table V.

Example. *Let it be required to find the dominical letter for* 1820, *old stile.* By looking for 1800 at the top of Table V. and 20 at the side, and guiding the eye to the angle of the column, D and C will be found to be the dominical letters for that year. Hence this year is leap year, which has always two dominical letters.

Table VI. *Containing the Dominical Letters for 4000 Years after the Christian Æra, new Stile.*

Years by which the given year exceeds the hundreds of years.	Hundreds of Years after Christ. 100 500 900 1300 1700 2100 2500 2900 3300 3700	200 600 1000 1400 1800 2200 2600 3000 3400 3800	300 700 1100 1500 1900 2300 2700 3100 3500 3900	400 800 1200 1600 2000 2400 2800 3200 3600 4000

28 56 84	D C	F E	A G	B A

Use of Table VI.

Example. *To find the dominical letter for the year* 1820, *new stile.* Enter Table VI. with 1800 at the head, and 20 at the side, and at the angle of the column will be found B A, the two dominical letters for that leap year.

The following Table is intended to shew the day of the month corresponding to any day of the week, or the day of the week corresponding to any day of the month for any year past or future.

TABLE VII. *Exhibiting the Days of the Months by the Dominical Letters, both for the Old and the New Stile.*

	25	26	27	28	29	30	

Use of Table VII.

The dominical letter for the given year being found from the preceding Tables, enter Table VII. with this letter at the head, and all the days in the column immediately below it will be Sundays; the days in the column on the right hand, if there is a right hand column, will be Mondays; and the days in the column on the left hand, if there is a left hand column, will be Saturdays; and so on with the rest.

On the epact.

The epact is the excess of the solar above the lunar year, or the number of days which, at any year of the moon's cycle, must be added to the lunar year, to make it equal to the solar year. Since the Julian year is 365^d 6^h, and the Julian lunar year 354^d 8^h 48′ 36″, the epact for the first year of the lunar cycle will be 10^d 21^h 11′ 22″, or nearly 11 days. The epact for two years will be 22 days, and for three years 33 days, or, deducting 30, it will be 3 days. Hence we shall have the following Table, containing the epacts as established by the Council of Nice, A. D. 325.

Golden Number.	Julian Epacts.	Golden Number.	Julian Epacts.	Golden Number.	Julian Epacts.
1	XI.	8	XXVIII.	15	XV.
2	XXII.	9	IX.	16	XXVI.
3	III.	10	XX.	17	VII.
4	XIV.	11	I.	18	XVIII.
5	XXV.	12	XII.	19	XXIX.
6	VI.	13	XXIII.		
7	XVII.	14	IV.		

But as the difference between the Julian and Gregorian years is equal to 11 days, the excess of the solar above the lunar year, the Gregorian epact for any year will be the same as the Julian epact for the preceding year; and hence we shall have the following Table:

Golden Number.	Gregorian Epacts.	Golden Number.	Gregorian Epacts.	Golden Number.	Gregorian Epacts.
1	XXX.	8	XVII.	15	IV.
2	XI.	9	XXVIII.	16	XV.
3	XXII.	10	XIX.	17	XXVI.
4	III.	11	XX.	18	VII.
5	XIV.	12	I.	19	XVIII.
6	XXV.	13	XII.		
7	VI.	14	XXIII.		

The following Table contains the Gregorian epact for years when the golden number is 1; and, therefore, to find the epact for any intermediate year, we have only to add 11 for every successive year, and subtract 30 as often as is necessary:

Gregorian Years.	Epact.	Gregorian Years.	Epact.
From 1600 to 1700	1	From 3100 to 3400	24
1700 1900	30	3400 3500	23
1900 2200	29	3500 3600	22
2200 2300	28	3600 3700	23
2300 2400	27	3700 3800	22
2400 2500	28	3800 4100	21
2500 2600	27	4100 4200	20
2600 2900	26	4200 4500	19
2900 3100	25	4500 4700	18

Universal rule for finding the Epact.

' The following is an universal rule for finding the Gregorian epoch: Divide the number of centuries in any year by 4, multiply the remainder by 17, and to this product add 43 times the quotient and the number 86, and divide this sum by 25. The quotient thus found being subtracted from the golden number, multiplied by 11, will leave a remainder, which, after the thirties are taken from it, will be the epact required.

Gauss' New Method of finding Easter.

Gauss' infallible method of finding Easter.

The following very curious and infallible method of finding the time of Easter, without any reference to the lunar motions, was discovered by the celebrated German mathematician M. Gauss, and is suited either to the Gregorian or the Julian calendar.

The values of A and B are constant in the Julian calendar.	Value of A.	Value of B.
	15	6
In the Gregorian calendar.	Values of A.	Values of B.
From 1582 to 1699	22	3
1700 . . . 1799	23	3
1800 . . . 1899	23	4
1900 . . . 1999	24	5
2000 . . . 2099	24	5
2100 . . . 2199	24	6
2200 . . . 2299	25	0
2300 . . . 2399	26	1
2400 . . . 2499	25	1

By the aid of the preceding Table, and the following rules, the time of Easter may be thus found. Having taken out the values of A and B from the Table, Chronology, Mathematical.

Divide the given year by . . . . . 19 and call the rem. a
. . . . the given year by . . . . . 4 . . . . b
. . . . the given year by . . . . . 7 c
. . . . the number $(19a+\text{A})$ . . 30 . . . . d
. . . . the number$(2b+4c+6d+\text{B})$ 7 . . . . e

Then the day of Easter will be $22+d+e$ of March.
or $d+e-9$ of April.

This rule is general for the Julian calendar, and has only two exceptions in the Gregorian calendar.

I. If the day of Easter, found by the rule, is the 26th of April, always make it the 19th of April.

II. If the day of Easter, found by the rule, is the 25th of April, always make it the 18th of April.

Example.—Let it be required to find the day of Easter, according to the Gregorian calendar, for 1813. It appears from the Table, that in this year $\text{A}=23$, and $\text{B}=4$, then we have

1813 divided by 19 leaves a remainder $=8=a$
1813 . . . . . . 4 . . . . $=1=b$
1813 . . . . . . 7 . . . . $=0=c$
$(19a+\text{A})=175$. 30 . . . . $=25=d$
$(2b+4c+6d+\text{B})=156$ 7 . . . . $=2=e$

Hence $22+d+e=49$th March, which is impossible. But $d+-9=18$th April, the day of Easter required

Table *of the Reciprocal Values of the principal Periods which are employed in Chronology.*

Seconds.												
60	Minutes.											
3,600	60	Hours.

250,029,648,000	4,197,160,800	69,952,680	2.914,695	416,385	95,760	7.980	1,995	1,596	1.140	$162\frac{6}{7}$	$79\frac{4}{5}$	Julian Period.

CHAP. II.

Historical Chronology.

Historical Chronology.

Historical Chronology is that branch of the science which treats of the æras and epochs fixed upon by different nations for determining the order of dates and of facts in their annals; or in a more extensive sense, it treats of all those historical documents, which are used for the purpose of establishing the existence of events, and the order in which they happened, such as Eclipses, Public Registers, Medals, Columns, Obelisks, Pyramids, Marbles, and Inscriptions. As many of these subjects, however, are treated under more appropriate heads than that of Chronology, we shall confine ourselves at present to the subject of Æras, Epochs, and Eclipses, as belonging more strictly to the present subject.

Table shewing the Principal Æras adopted by different Nations for determining the order of Dates.

Names of the Æras.	Years of the Vulgar or Christian Æra.	Abridged method of writing them.	Remarks.
Creation of the world.	4004 B. C. 4700 5872	A. M. Annus Mundi.	According to the Hebrew text. According to the Samaritan text. According to the Septuagint. This æra is adopted by the Greek church, and a great number of writers.
Olympiads.	776		Used by the Greeks for 1081 years, till A. D. 312, when Constantine substituted in its room the Æra of Indiction. The Greeks formerly marked their years by their Archons.
Foundation of Rome.	753	A. U. C. Anno Urbis Conditæ. P. R. C. Post Romam Conditam,	Used by the Romans till A. D. 250. The Romans formerly marked their years by their Consuls. Varro places this æra in B. C. 754, but the authority of the Capitoline Marbles is preferred.
Vulgar, or Christian æra.	0 A. D.	A. D. Anno Domini. B. C. Before Christ. A. C. After Christ.	Adopted by the greater number of writers.
Hegira.	622		Before the Hegira, the Arabians reckoned their years from the last war in which they were engaged. The word Hegira signifies *fled*, because during the night between the 15th and 16th of July, Mahomet fled from the persecution of his enemies from Mecca to Medina.
New French Æra.	1792		Adopted by the French at the foundation of their republic.
Æra of Callisthenes.	2234 B. C.	Minor Æras.	Adopted by some historians.
Æra of Nabonassar.	747		Used by Ptolemy, and Censorinus the chronologist. It received its name from having begun in the reign of Nabonassar.
Æra of the Seleucidæ.	312		This æra, which was followed by the Syrians and by the Jews established in Syria, derived its name from Seleucus Nicanor, because it began upon the day on which that prince entered Babylon.
Æra of Spain.	38		This æra was adopted by the Spanish writers, till 1415, when it was abolished by Peter of Arragon.
Æra of Actium.	30		Adopted in Egypt after the battle of Actium, and found upon several medals.
Æra of Dioclesian. Æra of the Martyrs. Æra of the Abyssinians.	284 A. D.		This æra was adopted by those who had followed the æra of Actium. It received the first name from the minions of Dioclesian, the second from the Christians who were persecuted under his reign, and the third because it was used by the Christians in Abyssinia.
Æra of Yezdejerd.	632		Adopted by the Persians of the middle ages, and named from Yezdejerd, the last king of the second empire of the Persians.
Æra of Geladdin.	1079		This æra succeeded the preceding æra in Persia, and received its name from the Sultan Gelaleddin, who reformed the Persian calendar in 1079, and made it nearly equal to the Gregorian calendar.

The following Table will shew the leading Epochs which are employed by the great Majority of Historians for determining the order of Facts.

Names of the Epochs.	Epochs.	Duration of the Epochs.	Observations.
The creation of the world	4004	1656	According to the Hebrew text.
The universal deluge	2348	427	
The calling of Abraham	1921	430	
The migration of the Israelites from Egypt	1491	479	Sacred History.
The temple of Jerusalem founded by Solomon	1012	476	
The first year of the reign of Cyrus over the greater part of Asia till the Christian æra	536	536	
The creation of the world	4004	2240	
The deluge of Ogyges	1764	507	
Expedition of the Argonauts	1263	79	
Burning of Troy	1184	408	
Æra of the Olympiads	776	240	Ancient History.
First year of the reign of Cyrus	536	224	
Æra of the Seleucidæ	312	312	
Christian æra	0	312	Muratori and the authors of the Universal History begin Modern History from this epoch.
The reign of Contantine at the æra of Indiction	312	94	
The invasion of the Roman empire by the Barbarians	406	76	
The foundation of the French monarchy	482		Millot begins *Modern History* from this epoch.
The restoration of the Western Empire	800	162	
Otho the Great obtains the empire	962	111	
The Pontificate of Gregory VIII.	1073	125	The first ten epochs of Modern History form what is called the History of the Middle Age.
The Pontificate of Innocent III.	1198	172	
The death of St Louis	1270	108	
The great schism of the West	1378	75	Modern History.
The taking of Constantinople by Mahomet II.	1453	66	
Charles V. obtains the empire	1519	44	
The Council of Trent ends	1563	40	
The Union of the Crowns of Scotland and England .	1603	85	
Revolution in England	1688	60	
Treaty of Aix-la-Chapelle	1748	41	
French Revolution	1789	13	
Treaty of Amiens	1802		

The following Table contains the principal Eclipses noticed by Historians, as having been either preceded, accompanied, or followed by some great event.

Luminary Eclipsed.	Times when they happened.	Remarkable Events by which these Eclipses were accompanied.
	Year.	
SUN.	776, 16th Oct. B. C.	Two months after the celebration of the Olympic games, which served for the date of the æra of the Olympiads.
SUN.	772, 24th June.	It preceded the year of the birth of Romulus.
SUN.	753, 5th July.	According to an old calendar, this eclipse happened on the 21st of April, the very day on which the foundations of Rome were laid.
MOON.	721, 19th March.	This eclipse was total. The Assyrian empire ended, and the Babylonian empire began.
SUN.	715, 24th May.	Romulus died in the same year.
SUN.	585, 28th May.	This eclipse was predicted by Thales. Cyaxares, king of Media, and Heliates III. king of Lydia, were so much terrified at this eclipse, that in the very heat of an engagement, they threw down their arms, and made peace.
MOON.	523, 16th July.	This eclipse, which was observed at Babylon, preceded the death of Cambyses, king of Persia.
MOON.	502, 19th Nov.	This eclipse was followed by the slaughter of the Sabines, and the death of Valerius Publicola.
SUN.	481, 19th April.	This eclipse happened at the very instant when Xerxes set out from Sardis on his expedition against Greece.
SUN.	464, 30th April.	This eclipse was followed by the assassination of Xerxes by Artabanes.

Continuation of the preceding Table.

Luminary Eclipsed.	Times when they happened.	Remarkable Events by which these Eclipses were accompanied.
	Year.	
MOON.	431, 25th April.	This eclipse was followed by a great famine, and by the Peloponnesian war.
SUN.	431, 30th Aug.	This eclipse, which was total, was accompanied with a comet, and a plague at Athens.
MOON.	413, 27th Aug.	Nicias, the Athenian general, was defeated before Syracuse.
SUN.	394, 14th Aug.	Conon, the Athenian general in the service of Persia, gains a naval victory over the Lacedemonians at Cnidos.
MOON.	331, 21st Sept.	This eclipse happened 11 days before the battle of Arbela, in which Darius was routed by Alexander.
SUN.	310, 15th Aug.	Agathocles carried the war into Africa.
SUN.	190, 14th March.	Scipio Asiaticus sets out for Asia.
MOON.	168, 28th June,	This eclipse happened in the same night in which Paulus Emilius conquered Perseus, king of Macedon.
SUN.	50, 7th Mar. A.D.	This eclipse happened when Julius Cæsar passed the Rubicon.
SUN.	31, 27th Sept.	This eclipse happened 14 days before the battle of Actium.
SUN.	14, 20th Aug.	This eclipse happened the day after the death of Augustus.
SUN.	59, 30th April.	Agrippina assassinated by order of her son Nero.
SUN.	237, 12th April.	This total eclipse was followed by a sixth persecution of the Christians.
SUN.	306, 27th July.	The stars were seen during this eclipse, and the emperor Constantius died on the 25th July.
SUN.	840, 4th May.	Louis le Debonnaire died six weeks after this eclipse.
SUN.	1009, 29th June.	Jerusalem taken by the Saracens.
SUN.	1133, 2d August.	The stars were visible during this eclipse, which was accompanied by a schism in the church, occasioned by there being three popes at once.

CHAP. III.

Comparative Chronology.

COMPARATIVE Chronology is that branch of the sciences which treats of the comparison of different æras, and is of the greatest importance in facilitating the study of history. Our limits will not permit us to enter so fully into this subject as we could have wished; but by treating it in a tabular form, we shall be able to condense into one view the most important and useful information.

The following Table will point out the relation between the principal æras which are used in history; omitting the minor æras in p. 413, which are very seldom employed by historians:

The creation of the world corresponds to	The year 4004 before Christ. The year 710 of the Julian Period. The year 3251 before the foundation of Rome. The year 5996 before the French Æra.
The 1st year of the Olympiads corresponds to	The year 776 before Christ. The year 3228 of the Creation of the World. The year 23 before the foundation of Rome. The year 3938 of the Julian Period. The year 2568 before the French Æra.
The foundation of Rome corresponds to	The year 753 before Christ. The year 3251 of the Creation of the World. The year 4 of the 6th Olympiad. The year 3961 of the Julian Period. The year 2545 before the French Æra.
The vulgar, or Christian æra, corresponds to	The year 4004 of the Creation of the World. The year 1 of the 195th Olympiad. The year 753 of the foundation of Rome. The year 4714 of the Julian period. The year 1792 of the French Æra.
The Hegira corresponds to	The year 622 of the Christian Æra. The year 4626 of the Creation of the World. The year 3 of the 348th Olympiad. The year 1375 of the foundation of Rome. The year 5336 of the Julian Period. The year 1206 before the French Æra.

The æra of the French Republic, corresponds to
The year 1792 of the Christian Æra.
The year 5796 of the Creation of the World.
The year 1 of the 643d Olympiad.
The year 2545 of the foundation of Rome.
The year 1206 of the Hegira.
The year 6506 of the Julian Period.

Use of the preceding table.

By means of the data in the preceding Table, we may easily convert the years of any one æra in those of another; and as the method of doing this is frequently of the greatest use, we shall illustrate it by a few examples.

Example 1. Cyrus took Babylon in the year of the world 3466; to what Olympiad does this year correspond?

Make $a =$ the given year, $e =$ the corresponding epoch in the Table, diminished by 1. Then the Olympiad will be $\frac{a-e}{4}-1$, the remainder being the year of the Olympiad. Thus, in the preceding example, the formula will become $\frac{3466-3227}{4}-1=59$ with a remainder of 3, which shews that the event happened in the 3d year of the 59th Olympiad.

Example 2. Socrates died in the 1st year of the 95th Olympiad; in what year of the world did this event happen?

Let a be the number of the Olympiad, b the year of the Olympiad, and c the corresponding epoch diminished by 1. Then the year of the world will be $\overline{a-1}\times 4+b+e$, or $4a-4+b+e$, which gives for answer 3604.

Example 3. To what year of the Christian æra does the 4th year of the 74th Olympiad correspond?

The letters denoting the same things as before, we have $\overline{a-1}\times 4+b-e$, or $4a-4+b-e$, which gives the year of Christ required, 481.

The formula in Example 2, and 3, is general for the translation of Olympiads into the years of other æras, or *vice versa*, with this difference only, that when the other æra is after the Olympiads, the quantity e is negative, and has the sign $-$; whereas when the other æra is before the Olympiads, the quantity e has the sign $+$.

It would be an endless task to multiply examples for all the other æras; but those who wish to draw up rules for themselves, will derive assistance from the following Table, which comprehends also some of the minor æras mentioned in page 413.

The death of Socrates, which happened in the 1st year of the 95th Olympiad, happened also in the	Year of the World	3604
	Year of Rome	354
	Year of the Julian Period	4314
	Year before the French Æra	2192
	Year before Christ	400
The Peace of Westphalia, which happened in the year of the world 5652, happened also in the	4th year of Olympiad	606
	Year of Rome	2401
	Year of Christ	1648
	Year of the Hegira	1058
	Year of the Julian Period	6362
	Year before the French Æra	144
The Peace of Amiens, signed in the year 1802 of Jesus Christ	Year of the world	5806
	2d Year of Olympiad	545
	Year of Rome	1555
	Year of the Hegira	1217
	Year of the Julian Period	6516
	Year of the French Æra	10
	Year of the Æra of Callisthenes	4036
	Year of the Æra of Nabonassar	2549
	Year of the Æra of the Seleucidæ	2114
	Year of the Æra of Spain	1840
	Year of the Æra of Actium	1832
	Year of the Æra of Dioclesian	1518
	Year of the Æra of Yezdejerd	1170

CHAP. IV.

Tabular Chronology.

Tabular chronology.

Tabular Chronology, is that branch of the science in which all the leading events recorded in history are arranged in a chronological order, or in the order of time in which they happened. Along with the great political events which accompany the rise and fall of empires, these tables ought to include the leading facts in the arts and sciences—the most striking natural phenomena, such as total and central eclipses, the appearance of comets, unusual conjunctions of the planets, the fall of meteoric stones, meteors, hurricanes, inundations, volcanic eruptions, &c.—and an account of the philosophers, statesmen, and warriors, who have acted a leading part in the revolutions of kingdoms and of science. By this means we obtain, at one glance, a general view of the various steps in the progress of society, and the eye of the reader becomes a useful auxiliary to his memory and judgment.

In drawing up the following Table, we have obtained great assistance from the Chronological Tables of Blair, Playfair, and Chantreaux; but we have presented the various events in the most abridged form, and have thus made room for many new and curious facts and phenomena which have never before been included in Chronological Tables.

A

CHRONOLOGICAL TABLE

FROM THE

CREATION OF THE WORLD TO THE YEAR 1813.

[In the following CHRONOLOGICAL TABLE, we have inserted a variety of interesting facts respecting the progress of the Arts and Sciences, which have never appeared in any System of Chronology. We have likewise added a number of curious Celestial Phenomena; and all the instances which have occurred, from the earliest times, of the fall of Meteoric Stones. For this interesting class of Atmospherical Phenomena, the Editor has been indebted to THOMAS ALLAN, Esq. F. R. S. E. who has kindly permitted him to make use of his Manuscript Paper on this subject, which contains the fullest and most correct account of Meteoric Stones that has yet been drawn up. In another part of our Work, we hope to have it in our power to present our readers with Mr Allan's valuable Paper.]

B. C.

4004. THE world created at the autumnal equinox, on Sunday, October 23.
5872, according to the Septuagint.
4700, according to the Samaritan text.
Adam and Eve created on Friday, Oct. 28.
4003. Cain born.
3875. Abel is murdered by Cain.
3874. Seth born.
3382. Enoch born;—translated to heaven, 3017, æt. 365.
3317. Methusalem born. He died at the age of 969.
2948. Noah born. He died at the age of 950.
2446. Shem born. He died at the age of 600.
2349. Noah entered the ark on Sunday, Nov. 30, and it began to rain on Sunday, Dec. 7.
2348. The deluge. On Wednesday, May 6, the ark rested on mount Ararat. On Friday, Dec. 18, Noah left the ark.
2247. The tower of Babel is built in the valley of Shinar by Noah's posterity;—the confusion of their languages, and their dispersion among different nations.
2234. Astronomical observations begun at Babylon, a register of which was transmitted by Callisthenes to Aristotle for 1903 years to the capture of that city by Alexander in the year 331 B. C.
2221. Nimrod founds the Chaldean monarchy.
2205. The first imperial dynasty of China called Kia begins. See *Mem. Inscript.* tom. xviii. p. 220.
2188. The kingdom of Egypt commences under Menes or Misraim, which lasted for 1663 years, to the conquest of Cambyses, in the year 525 B. C.
2089. The kingdom of Sicyon established, which lasts 1000 years.
2059. The kingdom of Assyria begins.
1996. Abraham born. He died 1821, B. C. æt. 175.
1897. Circumcision instituted. The cities of Sodom, &c. destroyed.
1896. Isaac born.
1856. The kingdom of Argos begins.
1827. The 17th dynasty of the six shepherd kings in Egypt begins, and continues 103 years.
1822. The letters invented by Memnon, the Egyptian.
1796. The reign of Ogyges begins.
1766. The second imperial dynasty of China called Chang begins.

B. C.

1764. The deluge of Ogyges, which laid waste Attica for more than 200 years.
1759. Jacob goes to Haran, and marries the two daughters of his uncle.
1728. Joseph sold into Egypt.
1718. Sparta built by Spartes. See *Rollin.*
1702. All the lands in Egypt sold to Joseph.
1689. Jacob predicts the coming of the Messiah, and dies æt. 147.
1635. Joseph foretels the egress of the Israelites from Egypt, and dies æt. 110, having been præfect of Egypt for 80 years.
1615. The Ethiopians from the Indus settle near Egypt.
1582. The chronology of the Arundelian marbles begins, when Cecrops is supposed to have come into Attica.
1575. Pharaoh orders all the children of the Israelites to be drowned.
1571. Moses born.
1570. Pyramids of Egypt built.
1556. Cecrops, with a colony of Saites from Egypt, founds Athens.
1546. About this period Scamander comes from Crete and founds Troy.
1531. Moses visits the Israelites; flies into Midian, and continues there 40 years.
1503. The deluge of Deucalion in Thessaly, placed by the Arundelian marbles in 1521.
1500. First eruption of Ætna. See *Collection. Academique,* tom. vi. p. 489.
1497. The council of Amphictyons established.
1493. The Phœnician letters carried into Greece by Cadmus, who built the citadel of Thebes.
1491. God appears in a burning bush to Moses, and sends him into Egypt. Moses opened a passage for the Israelites through the Red Sea.
1485. The first ship that appeared in Greece, brought from Egypt by Danaus. The pump supposed to have been invented.
1480. Troy supposed to have been built by Dardanus.
1453. The first Olympic games celebrated at Elis.
1451. Moses dies, æt. 110.
1445. Joshua partitions the land of Canaan.
1426. Joshua dies at Timnath-Serah, æt. 110.
1406. Minos gives laws to Crete. Iron found from

B. C.

the burning of the woods of mount Ida in Crete.

1390. Benjamin almost destroyed by the other 11 tribes.

1383. Ceres taught the Athenians the arts of agriculture, &c.

1356. The Eleusinian mysteries introduced at Athens.

1344. The kingdom of Mycenæ begins about this time, when the kingdom of Argos was divided.

1326. The Isthmian games instituted by Sysiphus.

1325. The great Egyptian canicular year began on Saturday, July 20, and consisted of 1460 years.

1307. The Olympic games instituted by Pelops.

1300. The Lupercalia instituted.

1285. Deborah defeats the Canaanites under Sisera.

1284. The Siculi pass out of Italy into Sicily; according to others, the first colony arrived in 1294, and a second in 1264.

1263. The expedition of the Argonauts;—according to others, in 1225. About this time the Pythian games were instituted by Adrastus.

1252. The city of Tyre built.

1245. Gideon routs the Midianites.

1243. Arcadians conducted by Evander into Italy.

1234. Theseus establishes a democracy in Attica, and renews the Isthmian games; others say in 1231.

1233. Carthage built by a colony of Tyrians.

1225. The Theban war of the 7 heroes against Eteocles.

1222. The celebration of the Olympic games by Hercules.

1213. Helen carried off by Theseus.

1198. Helen carried off by Paris; others say in 1204.

1194. The Trojan war begins, and continues 10 years.

1188. Jephtha, the 7th judge of Israel for 6 years, his rash vow with respect to his daughter.

1184. Troy burned by the Greeks, on the 11th of June, 408 years before the first olympiad. Æneas sails early in autumn for Thrace.

1182. The kingdom of the Latins begins under Æneas.

1179. The maritime power of the Mediterranean acquired by the Lydians.

1176. Salamis in Cyprus built by Teucer.

1157. Eli the high priest, 11th judge of Isael for forty years.

1152. The city of Alba-Longa built by Ascanius.

1141. The Amazons burned the temple of Ephesus.

1136. Samson slays 3000 Philistines.

1124. The migration of the Æolian colonies. Thebes built by the Bœotians.

1122. The 3d dynasty of China, called Tcheou, begins.

1115. The mariner's compass said to be known in China.

1104. The Heraclidæ return into Peloponnesus; and divide it. The kingdom of Lacedæmon begins. That of Mycene ends.

1088. The kingdom of Sicyon ends; others say in 1130.

1070. Athens governed by archons.

1058. The maritime power of the Mediterranean acquired by the Pelasgians.

1055. Saul kills himself on mount Gilboa.

1048. Jerusalem taken by David; and made the seat of his kingdom.

1044. The Ionian colonies migrate from Greece.

1023. Absalom rebels, and is killed by Joab.

1012. Solomon begins to build the temple.

000. The maritime power of the Mediterranean acquired by the Thracians, who hold it 19 years.

996. Solomon's fleet prepared in the Red Sea, and sent to Ophir.

992. Solomon's palace finished.

B. C.

986. Samos, in the island of the same name, and Utica, built about this time.

975. The kingdoms of Judah and Israel divided.

974 or 971. Sesac, king of Egypt, takes Jerusalem, and plunders the temple.

926. Lycurgus, the Spartan lawgiver, born.

916. The maritime power of the Mediterranean acquired by the Rhodians, who maintain it 23 years.

907. Homer wrote his poems and flourished.

900. The kingdom of Assyria ends.

896. Elijah the prophet taken up into Heaven.

893. The maritime power of the Mediterranean acquired by the Phrygians.

884. Lycurgus, after travelling 10 years, establishes his laws in Lacedæmon. The Olympic games restored at Elis.

872. The art of sculpture in marble said to be invented.

869. Scales and measures invented by Phidon, king of Argos, who also coined silver at Ægina. The city of Carthage built by Dido; others say it was enlarged by her in 864.

868. The Cyprians acquire the maritime power of the Mediterranean.

839. The kingdom of Judah desolated by the army of Hazael, king of Syria.

826. The maritime power of the Mediterranean acquired by the Phœnicians.

820. Nineveh taken by Arbaces, and Belesis; Sardanapalus burns himself to death.

814. Kingdom of Macedon begins, and continues 646 years, till the battle of Pydna.

801. Capua, in Campania, built.

797. Kingdom of Lydia begins.

790. Amos the prophet flourished. He prophesied in 787.

787. The Egyptians acquire the maritime power of the Mediterranean.

786. The Corinthians invented ships called Triremes.

779. The race of kings terminated at Corinth, and was succeeded by magistrates, called Prytanes elected annually.

770. Phul invades the kingdom of Israel, and is bribed to depart with 1000 talents.

760. Theopompus establishes the Ephori at Lacedæmon.

754. The decennial archons begin at Athens. The Milesians acquire the maritime power of the Mediterranean.

753. Rome built, according to Varro, April the 20th. or the 12th of the kalends of May.

750. The rape of the Sabines.

747. Union of the Romans and Sabines. The æra of Nabonassar begins.

743. The first war between the Messenians and Lacedæmonians begins, and continues 19 years.

734. The Carians acquire the command of the Mediterranean.

732. Syracuse built by a colony of Corinthians under Archias; others say in 758.

724. The first Messenian war ended by the capture of Ithome, which subjected them to the Lacedæmonians.

722. The Chinese empire divided into principalities. Confucius's history of China begins.

721. Samaria taken, after three years siege. The first eclipse of the moon on record, according to Ptolemy, March 19th, 3 hours 20′ before midnight.

720. The 2d and 3d eclipse of the moon on record; the

B. C.

2d on March 5th, 50′ before midnight; and the 3d on September 1st, 4 hours 20′ before midnight, according to the meridian of Alexandria.

717. Unsuccessful siege of Tyre for about five years by Salmanaser king of Assyria.

713. Gela in Sicily founded. Senacherib's army destroyed in one night by an angel, to the amount of 185,000 men.

709. The Salii, an order of priests, instituted by Numa.

708. Ecbatana built by Dejoces.

707. Tarentum built by the Parthenians, on being expelled from Sparta.

703. Corcyra built by the Corinthians.

696. Isaiah sawn asunder by order of Manasses.

690. Holofernes besieged Bethulia, and killed by Judith.

686. Archilochus invented the Iambic verse.

685. The Messenian war continues from 685 to 671.

684. Athens governed by annual archons. Tyrtæus the poet flourished.

683. The Lacedæmonians defeated by Aristomenes.

680. Assaradinus king of Assyria, takes Babylon. The chariot race instituted at the Olympic games.

678. Dejoces extends Media to the river Halys.

677. Manasseh king of Judah carried prisoner to Babylon.

676. The Lesbians acquire the command of the Mediterranean, and retain it about 69 years.

675. The annual festivals of Carnia instituted at Sparta. Terpander the poet the first victor.

673. Terpander added three strings to the lyre. Thaletas of Gortynius, in Crete, the musician.

671. The second Messenian war finished, and the Messenians driven from the Peloponnesus.

670. Alcman of Sardis, the lyric poet.

667. The combat between the Horatii and the Curiatii.

665. The city of Alba destroyed. The Messenians settled in Italy. War between the Romans and the Fidenates.

659. Cypselus usurps the government of Corinth, and retains it for 30 years.

658. Byzantium built by a colony of Argives. Others place the building of it in 670.

652. A shower of meteoric stones fell at Mount Alba.

651. A five years' war between the Romans and Sabines begins. Cyrene in Africa founded.

648. The Thoth of the year of Nabonassar was on February 1st, having shifted 25 days in 100 years.

641. Amon, king of Judah, slain by his servants.

636. The Tartars defeat the Chinese with great slaughter.

631. War between the Romans, and the Fidenates and Sabines, which continues for fifty years.

630. Cyrene built by Battus, who begins that kingdom.

629. The government of Corinth usurped by Periander.

627. Jeremiah the prophet flourished.

626. Zephaniah the prophet flourished.

625. The Pentateuch found by Hilkiah.

624. The Scythians invade Media, Lydia, &c. Draco the lawgiver, archon at Athens.

623. Draco establishes his laws at Athens.

621. War between the Lydians and Milesians, which continues 11 years. The fourth eclipse on record, which was of the moon, on Saturday April 22d, three hours after midnight, according to the meridian of Alexandria.

610. Necho begins the canal between the Nile and the Red Sea.

B. C.

608. Josiah, king of Judah, killed at Megiddo by Pharaoh Necho, king of Egypt.

607. Alcæus the poet flourished.

606. Nineveh destroyed by the armies of Cyaxares and Nabopolassar.

605 or 606. The first captivity of the Jews.

604. The Phœnicians about this time sail from the Red Sea round Africa, and return by the Mediterranean.

600. Sappho the Lyric poetess flourished.

596. The Scythians expelled from upper Asia, by Cyaxares. Epimenides of Crete, the first builder of temples in Greece.

594. Solon, archon and lawgiver of Athens. Thales of Miletus.

593. Ezekiel the prophet flourished.

592. Anacharsis the Scythian flourished.

591. The Pythian games first celebrated at Delphi.

590. The Lydian war begins, and continues six years.

587. The city of Jerusalem taken by Nebuchadnezzar.

586. The temple of Jerusalem burned.

585. A battle upon the river Halys between Cyaxares and Halyattes, interrupted by an eclipse of the moon, May the 28th, predicted by Thales. Æsop the mythologist flourished.

582. The Isthmian games restored.

580. Money first coined in Rome.

579. The Megarensian war. Stesichorus the poet flourished.

572. Tyre taken by Nebuchadnezzar.

571. Apries, king of Egypt, dethroned by Nebuchadnezzar.

569. Daniel interpreted Nebuchadnezzar's dreams according to Josephus.

568. The Nemæan games restored. Anaximander of Miletus, and Phalaris tyrant of Agrigentum flourished.

566. The first census at Rome—84,700 citizens.

562. The first comedy at Athens, acted upon a scaffold by Susarion and Dolon.

560. Pisistratus usurped the tyranny of Athens, which he recovered after expulsion in 557, and from which he was again expelled in 556.

559. Daniel delivered his predictions. Cyrus ascended the Persian throne.

556. Anaximenes of Miletus flourished.

550. Cyrus king both of Media and Persia. The kingdom of Lydia ended.

549. Theognis the poet flourished. The Pisistratidæ burn the temple of Apollo at Delphos.

548. Crœsus crossing the Halys by an artificial bridge contrived by Thales, is routed by Cyrus.

539. The Phocæans settle in Gaul, and build Marseilles. Pythagoras flourished.

538. Cyrus takes Babylon, and terminates the kingdom of Babylon.

537. Simonides of Cea, the poet, flourished.

536. Cyrus issues an edict for the return of the Jews and the rebuilding of the temple. Thespis the inventor of tragedy lived.

535. The first tragedy acted about this time at Athens, by Thespis in a waggon. According to the Arundelian marbles in 536.

532. Anacreon the poet flourished.

530. Cyrus marches against the Scythians.

527. Learning encouraged at Athens. A public library first founded. War between the Romans and Sabines.

B. C.

526. Cambyses conquered Egypt. A comet appeared in China, near Antares, or *a Scorpionis*, and extended to the milky way.
523. The 5th lunar eclipse observed at Babylon, on Wednesday, July 16th, one hour before midnight, and more than 6 digits eclipsed on the northern disk.
520. Confucius lived. The 2d edict to rebuild Jerusalem.
519. A great earthquake in China.
515. The temple of Jerusalem finished March 10. The passover celebrated, April 18.
512. Babylon revolts from Darius, but is recovered two years after.
510. The tyranny of the Pisistratidæ abolished at Athens.
509. The consular government begins at Rome, on the expulsion of Tarquin and his family, Feb. 26.
508. First alliance between Rome and Carthage.
507. The second census in Rome—130,000 citizens.
506. Heraclitus the philosopher lived. Megabysus subdues Thrace and Macedonia. War between the Romans and Sabines.
505. Parmenides of Elea, the philosopher, lived.
504. Sardis burned by the Athenians, which occasioned the invasion of Greece by the Persians.
502. The sixth lunar eclipse observed at Babylon on Monday, Nov. 19, 24′ before midnight—3 digits eclipsed on the south part of the disk.
498. The Ionians, after a revolt, subdued by the Persians, and Miletus taken.
497. The Saturnalia instituted at Rome—150,700 citizens.
495. Tarquin the proud dies at Cuma.
494. War between the Romans and Sabines.
493. Tribunes created at Rome. The Athenians build the port of Piræus.
491. The kingdom of Syracuse usurped by Gelo. Coriolanus banished from Rome. The seventh lunar eclipse observed at Babylon, on Wednesday, April 25—2 digits of the moon's south limb eclipsed.
490. The Persians defeated by Miltiades, at Marathon.
488. Coriolanus withdraws the Volsci from Rome.
487. Egypt rebels, and revolts from the Persians.
486. Æschylus first gains the prize of tragedy.
485. Cassius punished for usurping the sovereignty. The Volsci and Æqui subdued.
484. Aristides banished from Athens. Xerxes recovers Egypt.
483. Quæstors first created at Rome. An eruption of mount Ætna.
481. Xerxes begins his expedition against Greece.
480. The affair of Thermopylæ finished, Aug. 7th. The Persians defeated at Salamis in a sea-fight, Oct. 20th. Pindar the lyric poet flourished, ob. 435, æt. 86. A comet appeared with a curved tail, according to Lubiniezki.
479. The Persians defeated at Platæa, Sept. 22; on which day happened the battle of Mycale. War between the Romans and Hetrurians. Charon of Lampsacus, the historian, lived.
477. The 300 Romans, of the name of Fabius, killed by the Veientes near Cremona, July 17.
476. Valerius triumphed over the Veientes and Sabines, 103,000 citizens in Rome. A great eruption of mount Ætna.
471. Themistocles retires to Xerxes in Asia.
470. Cimon defeats the Persian fleet at Cyprus, and the army near the river Eurymedon in Pamphylia. An eruption of Mount Ætna. Anaxagoras of Clazomene, the philosopher, ob. 420, æt. 72.

The Austrians completely defeated by the French at the battle of Wagram, July 5, 6. Suspension of hostilities between France and Austria, July 12. Surrender of Senegal to the British, July 20. Battle of Talavera between the British and French, July 27. The British troops, after landing in Walcheren, July 30, take Middleburg, July 31; and Flushing, Aug. 15. Peace between Russia and Sweden signed, Sept. 17. Peace between France and Austria ratified, Oct. 15. The 50th anniversary of the King's accession celebrated in every part of the kingdom, Oct. 25. Lord Collingwood destroys 3 French ships of the line bound from Toulon to Barcelona, off Cape St Sebastian, Oct. 25. Bonaparte divorces his wife the Empress Josephine, Dec. 16.

1810. Bonaparte relaxes the Berlin and Milan decrees, Jan. 4. A shower of meteoric stones fell in Caswell county, North America, Jan 30. An earthquake at Malta, Feb. 16. Amboyna and its dependencies surrender to the British, Feb.

A. D.

17. Guadaloupe taken by the British, March 5. Lord Collingwood dies, March 7. Bonaparte marries the Princess Maria Louisa, daughter of the Emperor of Austria, April 1. Great riots in London, on the committal of Sir F. Burdett to the Tower, April 9. Crown Prince of Sweden dies, April 29. American non-intercourse act repealed, May 1. Mr Windham dies, June 4. Riot in Stockholm, at the funeral of the Crown Prince, June 20. Louis Bonaparte abdicates the throne of Holland, July 1. The Isle of Bourbon surrenders to the British, July 8. Holland annexed to the French empire, July 9. Ciudad Rodrigo taken by the French, July 10. A meteoric stone, weighing 7¾ pounds, fell in the county of Tipperary, Ireland, Aug. 10. An earthquake felt at St Michael's, one of the Azores, Aug. 12. Bernadotte chosen Crown Prince of Sweden, Aug. 21. A small comet discovered by M. Pons, 22d Aug. Lucien Bonaparte and his family taken by the Pomona frigate, Aug. 23. Almeyda surrenders to the French, Aug. 28. A great eruption of Mount Vesuvius, Sept. 10. Bonaparte issues a decree to burn all British merchandize, Oct. 19. Princess Amelia dies, Nov. 2. Gustavus Adolphus, the late King of Sweden, arrives at Yarmouth, Nov. 10. Three meteoric stones fell in the department of the Loiret, Nov. 23. Henry Cavendish, ob. æt. 78.

1811. Tortosa surrenders to the French, Jan. 1. Prince of Wales appointed Regent, Feb. 4. A meteoric stone, of 15 pounds, fell in the village of Konleghowsk, in the government of Tschernigoff, in Russia, on the 1st March. Battle of Barrosa, in which the French are defeated by the British under General Graham, March 5. Anholt defended by a handful of British sailors against the Danish flotilla, of 18 gun boats, and 4000 men. Badajos surrenders to the French, March 10. A small comet discovered by Flauguergues, 25th March. The French defeated by Lord Wellington in the battle of Fuentes de Honores, May 5th. General Beresford defeats the French under Soult in the battle of Albuera, May 16th. Action between the American frigate the President of 44 guns, commanded by commodore Rogers, and the British vessel the Little Belt of 18 guns, May 16th. Siege of Badajos raised, June 11th. Marshal Suchet takes Tarragona by assault, June 29th, and makes himself master of Montserrat, July 24th. The settlement of Batavia, the last colony of France, surrenders to the British under Sir Samuel Auchmuty, September 17th. The Boulogne flotilla defeated by the Naiad frigate in the presence of Bonaparte, Sept. 22d. General Blake defeated by the French under Suchet, Oct. 25. In consequence of this victory Murviedro surrenders to the French, Oct. 27th. General Hill surprises and routs the division of general Girard, Oct. 28th. A comet appears, Dec. 23d. The St George of 98 guns, and the Defence of 74 guns, stranded on the coast of Jutland, and the whole of the crews, amounting to 2100 men, perished, Oct. 24. The Hero of 74 guns stranded on a sand bank off the Texel, and the whole of her crew lost, Dec. 25th. General Blake defeated by the French near Valencia, Dec. 26th.

1812. The French defeated at Tariffa by colonel Skerret, Jan. 1st. Lord Wellington takes Ciudad Rodrigo by storm, Jan. 19th. Valencia surrenders to the French, along with the army under General Blake, Feb. 6th. A dreadful earthquake in the Caraccas, March 26th. Bonaparte makes proposals for peace, which are rejected, April 17th. Badajos taken by Lord Wellington, April 27th. Bonaparte sets out from Paris, to take the command of the army against Russia, May 9th. Mr Perceval shot in the lobby of the House of Commons, May 11th. America declares war against Britain, June 18th. Joseph Bonaparte evacuates Madrid, June 28th. Lord Wellington defeats the French under Marmont, near Salamanca. Preliminaries of peace signed between Britain, Russia, and Sweden. Orders in council revoked, June 23d. Revolution in Sicily, July 20th. Lord Wellington enters Madrid, Aug. 12. Marshal Victor besieges Riga, Aug. 13th. General Hull and the American army taken prisoners by General Brock, Aug. 17. Battle of Smolensko, between the French and Russians, Aug. 16. Battle of Mojaisk, in which the victory is claimed both by the French and Russians, Sept. 7. Soult raises the siege of Cadiz, Aug. 25th. A great and sanguinary battle fought at Borrodino, between the French and Russians, in which the victory is claimed by both sides, Sept. 7. The Russians burn Moscow, which the French enter, Sept. 14. Lord Wellington advances to Burgos, Sept. 21st. The French evacuate Moscow, and begin a disastrous retreat, Oct. 19th. Lord Wellington raises the siege of Burgos, Oct. 20th. Moscow re-occupied by the Russians, Oct. 22d. Bonaparte, after leaving his army at Smorgony on the 25th Nov. arrives in Paris on the 18th Dec. The French defeated at the passage of the Beresina, Nov. 28th. Wilna taken by the Russians, Dec. 10. Thirty thousand Prussians under General York join the Russian army, Dec. 30.

1813. The Conservative Senate of France agree to place 350,000 men at the disposal of the Minister of War, Jan. 11th. The House of Commons agree, by a majority of 40, in a House of 488, to go into a committee on the Catholic question, Mar. 2. The Russians enter Hamburg, Mar. 8, and Berlin, Mar. 10. The Russians defeat the French at Lunenburg under Morand, who is slain, April 2. Sir John Murray defeats the French under Suchet, at Castello, in Spain, April 13. Thorn surrenders to the Russians, April 16, and Spandau on the 18th April. Battle of Lutzen, in which the victory is claimed both by the French and the allies, May 2. The Roman Catholic bill lost at its third reading in the House of Commons, by a majority of four, May 24.

CHRONOMETER. See Timekeeper.

CHRONOMETER, in Music, an instrument for accurately measuring time. Of these, two different kinds are in use with musicians. One of them is for measuring the equal spaces of time, in which the bars and principal notes in any given piece of music are to be performed, in place of the signals of the coryphæus, mesochori, or manuductor of the ancients, and the motions of the maestro di capella, conductore, or leader of our modern performances, or concerts. The late Dr Robinson, in the *British Magazine*, vol. ii. p. 283, proposed the use of a graduated pendulum, for marking the lengths of the notes in performance, and gave a table of the lengths of pendulums for the notes of several of the most popular of Handel's songs, &c. The late Mr Clagget, and since him Mr Peck of Lombard street, sold a machine for *beating time*, as it is called among singers. The other kind of chronometer is useful to tuners of organs and piano fortes, being calculated, according to the suggestion of the late Dr Robert Smith, in his *Harmonics*, 2d edit. p. 210, to measure fractions of a quarter of a minute, or of one second in other machines, according to the calculated velocity of the Beats (see that article) of any particular system of temperament that is wished to be tuned. A simple, accurate, and general *beat-counter*, is still, however, a great desideratum with the tuners of organs, piano-fortes, harps, &c. (ε)

CHURCH History. See Ecclesiastical History.

CHURCHILL, John, Duke of Marlborough, the most successful general in English history, was the son of Sir Winston Churchill, and was born at Ashe in Devonshire in 1650. The course of his early education has not been accurately recorded, and it is probable, that he had acquired little beyond the elements of learning, when his father was induced to carry him, at the early age of twelve, to court. The hereditary loyalty of the family seemed to have paved the way for the appointment of young Churchill to those stations of which his years admitted, as he soon became a page to the Duke of York, and an ensign in the guards. His farther advancement was promoted by his comely person, his prepossessing manners, and, by a circumstance of less credit to his family, we mean, that of his sister being mistress to the Duke of York. She was the mother of the celebrated Duke of Berwick. Churchill's first opportunities of acquiring military knowledge were in the service of France, in which, in consequence of King Charles's unnatural alliance in 1672, a body of English auxiliaries served under command of the king's natural son, the Duke of Monmouth. Churchill was then a captain, and distinguished himself by many acts of bravery. Turenne was commander in chief, and young as Churchill was, it is probable that the tactics of that distinguished leader furnished him with much matter of reflection. Being equally in favour with the Duke of Monmouth and the Duke of York, he attained, before the end of the war, the rank of lieutenant-colonel. After the peace of Nimeguen, his official duties kept him a great deal about court; and though he was thought somewhat too free a speaker for that situation, he contrived to pass through those years of disquietude and civil dissension without committing himself with either party. His station was with the Duke of York; but, dependant as he was on his Royal Highness, he never thought of courting his favour by condescension on the score of religion.

In the year 1681 he became a married man, by espousing Miss Sarah Jennings, one of the maids of honour to the Princess Anne. Miss Jennings was then about 21, highly beautiful, and in great favour with her young mistress. Appearances thus seemed to promise much advantage from the match; and it is certain that Marlborough's ascendency over our councils in the early part of Queen Anne's reign, might have been less complete without the influence of his wife. But, on the other hand, we cannot help thinking it, on the whole, matter of regret, that he interfered at all with the business of the court. Had he confined himself strictly to his profession, his country might have had equal benefit from his services, and his character might have been free from the serious charge of wilfully prolonging the war. Certain it is, that his unfortunate failing, the love of money, was greatly aggravated by his wife's disposition; for several of those acts which drew odium upon him, proceeded evidently from her interference. In 1681, he obtained a regiment of dragoons, and was next year created Baron of Eymouth in Scotland. On James's accession in 1685, he was sent over on a short mission to France, and made an English peer by the title of Baron Churchill. He appears to have acted a prudent part during the three years of this infatuated reign, adhering to his own principles, and taking no share in the king's obnoxious acts. He was one of those, who sent over early an assurance of attachment to the Prince of Orange, and took an opportunity of joining him soon after he landed. On this occasion he thought proper to leave a letter to King James, lamenting the necessity of the step, ascribing it to the imperious dictates of conscience, and repeating, in the strongest terms, his attachment to the king personally.

After William's accession to the crown, Churchill was for some time in favour, being raised to the dignity of Earl of Marlborough, and entrusted, when William was in Ireland, with the command of the British auxiliaries in Flanders. It was in this summer, at the battle of Walcourt, that Marlborough first taught the French what they were to expect in future from his talents. Prince Waldeck, the commander in chief, declared, that "Marlborough saw more into the art of war in a day, than some generals in a course of years." Next year he distinguished himself in Ireland by the capture of Cork and Kinsale; acquisitions which tended to accelerate the conclusion of that miserable war. The year after 1691, he served under King William on the continent; but early in 1692 he was subjected to a very sudden loss of favour, his several offices being taken from him and given to others. His dismissal was followed by a still stronger measure, that of his commitment to the Tower, from which he was not released for several months. No public charge was brought against him, and the matter is still involved in uncertainty. Before this time differences had arisen between Queen Mary and her sister the Princess Anne. The Earl and Countess of Marlborough being attached to the latter, were sharers in her loss of court favour. King William had been elevated, in the fervour of the Revolution, to the utter exclusion of James's son; a step considerably beyond the calculations of those who called him over from Holland, and not rendered acceptable by any thing inviting or pleasant in William's manner. His confidence and his favour seemed to centre in foreigners, while English officers and noblemen were kept at a great distance. Sympathy for the fallen king operated in concurrence with these circumstances; and we accordingly find from Dalrymple and Macpherson's State Papers, that a secret correspondence was carried on by Godolphin, Russel, Marlborough, and other men of consequence, with the court of St Germains. To some discovery of this nature, was probably owing the disgrace of Marlborough. That family pique entered likewise into it is apparent, from the circumstance of an approximation between him and King William after the death of Queen Mary. It was evidently William's policy to be in good terms with a person so dear to the Princess Anne; but it is farther apparent, from the confidential business entrusted to Marlborough in the last three years of his reign, that all distrust of him was banished from his mind. At the approach of death, William, with whom opposition to France was always uppermost, recommended Marlborough as the most proper person to be entrusted with the command of the army destined to protect the liberty of Europe.

We are now arrived at the memorable æra in Marlborough's life, when the command of the allied forces, and the management of our foreign alliances, were vested in his person. This took place in the beginning of 1702, when he was in his 52d year, possessing the full advantage of matured experience, without any loss of constitutional activity. The unlimited favour of the queen, and the confidence of the allies, speedily acquired by engaging manners and brilliant successs, soon gave him a more complete controul over the military engine which he wielded than is common in a war of coalition. All this, however, was requisite; for France, flushed with former triumphs and recent acquisitions, was on the point of giving law to Europe. Louis XIV. had reigned forty years, and conducted three great wars, in the course of which the French armies had received hardly a single overthrow. At first he appeared to consider the campaign on the Dutch frontiers as a secondary part of the war, but Marlborough's progress soon taught him to view it in a different light. Had not the caution of the Dutch been opposed to offensive operations, there can be little doubt that the Duke, instead of merely taking fortified towns, and obliging the French to keep on the defensive during 1702 and 1703, would have accelerated the progress of the war, and inflicted on them a signal overthrow. It was not till 1704 that the Duke, being allowed to take the allied troops into Germany, and being consequently removed from unwise controul, shone forth in the true lustre of his talents. In that campaign he co-operated with Prince Eugene, with whom his uninterrupted cordiality is a circumstance highly honourable to both, and not often exemplified in military history. The victory of Blenheim was the first fruits of their harmony, and accomplished the deliverance of the emperor from imminent danger. Next year, Marlborough advanced towards the Moselle, on the plan of carrying on the war in the open country of Lorraine, and avoiding the delay inseparable from a succession of sieges. But this bold and judicious scheme was thwarted by the incurable slowness of the Germans, who failed in all their engagements, and made it necessary for the Duke to carry back the scene of operations into Flanders. It was on this occasion that Marshal Villars was first opposed to Marlborough. Villars was an able officer, and particularly skilful in the choice of defensive positions; but his vanity went beyond all bounds, and he took to himself the whole credit of the Duke's retreat, though it was owing chiefly to a different cause.

The year 1706 was destined to present a very different spectacle. The Duke had by this time, partly by weight of reputation, partly by his persuasive powers, succeeded in prevailing on the Dutch to leave him unfettered in the command of the allied troops. Though he could not, as he once intended, proceed to Italy with a force calculated to give to affairs, in that quarter, a turn similar to that of 1704 in Germany, he found means to send a body of Prussians to reinforce Prince Eugene, and afford him the means of acting on the offensive. This, along with the boldness of the Prince's tactics, led to the victory of Turin, and the deliverance of Piedmont. In the Low Countries, Marlborough signalized himself by the victory of Ramillies, a battle which, whether we consider it in itself, or in its results, was one of the most remarkable in history. It was planned altogether by himself, and was decided at a time of the day, which left sufficient room to follow it up effectually. The consequence was, the dispersion of the French forces, and the almost total fall of Austrian Flanders; all this too against an enemy who had marched to attack him in the full confidence of triumph. A decisive turn was now given to the war. Louis, humbled by the loss of Piedmont and Belgium, gave over the hope of dictating laws to Europe, and began to discover a disposition to peace. Next year, however, he threw an additional mass of force on the side of the Low Countries, which, joined to the cautious tactics of Vendosme, prevented Marlborough from making much progress. This, together with the success attendant on the French arms in Spain and in Provence, revived the hopes of that easily exalted people, and led, in 1708, to the resumption of offensive operations in Flanders. Marlborough was not long in making them repent their audacity, by the victory of Oudenarde, where daylight alone was wanting to make their loss as great as at Ramillies. Next came the siege of Lisle, an enterprise of great boldness, and prompted probably by Prince Eugene, who had now taken leave of Piedmont, and acted in Flanders along with Marlborough.

The year 1709 was remarkable for the dearly bought victory of Malplaquet, in which the loss on both sides, in killed and wounded, was hardly short of 40,000 men. This carnarge was occasioned by the nature of the French position, which, strong in itself, had been fortified with great care and expedition by Marshal Villars. The determination to attack it originated, there seems little doubt, with Prince Eugene. Such a measure accorded with his bold plan of war, and the responsibility is decidedly put on him in the book that goes by the name of his *Memoirs*, published in 1809, and which, whether proceeding from his pen or not, is evidently the work of a mind intimately conversant with the history of the war. The error, however, appears to have consisted, not so much in the determination to attack, as in the unfortunate delay in carrying it into effect. The allies had made a rapid and well-concerted movement for the investment of Mons, and Villars, commanding an equal force, set himself down in a position too near to allow of the siege being conveniently prosecuted. The movement of Villars took place on the 9th September, on which day, or on the next, it is generally thought the allies ought to have attacked him. But a reinforcement of 12,000 men being on the march, the battle was deferred till the morning of the 11th, without considering to what account the French were likely to turn so precious an interval. Marshal Boufflers had been sent from Paris to serve along with Villars, and though a senior officer, had no objection at this critical epoch of placing himself under his orders. In the course of the action, Villars was wounded and carried off the field, a circumstance to which he did not fail to ascribe the loss of the day. Next year, 1710, the French, taught by past disasters, kept on the defensive, though superior in number. Marlborough and Eugene held the joint command, and took the towns of Douay, Bethune, Aine, and St Venaut. In 1711, Eugene commanding on the Rhine, Marlborough acted alone. Villars was at the head of a very numerous army, and had carried his defensive labours, in the way of lines and trenches, to an extraordinary length. This, which was the last campaign of the Duke of Marlborough, though not distinguished by any battle, is probably that which a tactician would mark as the most brilliant æra in his career. By a series of feints and manœuvres, which it would greatly exceed our limits to recapitulate, he succeeded in deceiving Villars, active and experienced as he was, and in entering, without the loss of a man, those lines which the Marshal had boasted would prove his *ne plus ultra*. This signal exploit was followed by the siege of Bouchain, a place of great strength, and surrounded by inundations. Villars considered his reputation at stake, and repeatedly asserted that he would force the Duke to raise the siege. He durst not, however meet the Duke in a general action, and every other effort of relief was baffled by the Duke's vigilance and activity. Bouchain fell, and with its capture closed Marlborough's military career.

We are now to quit the scene of active operations, and take a retrospect of a less flattering nature. The Duchess of Marlborough having long considered herself the directress of the queen, forgot in her husband's prosperity, the moderation incumbent on a subject. She neglected a due attention to her sovereign, and opened the way for others to undermine her in the royal favour. The two principal agents of the political revolution which ensued, were Mrs Hill, afterwards Mrs Masham, and Harley, afterwards Earl of Oxford. The queen was earnestly desirous to be relieved from the domineering interference of the Duchess, but was very unwilling to lose the Duke's services. Hence, at one time, she found herself obliged to dismiss Harley, greatly against her will. But the humbled state of France, and the offers made by Louis for peace in 1709, joined to the enormous expenditure of war, gave weight to Marlborough's political opponents, and enabled the queen soon after to accomplish a change of ministry. Her husband's death, her own infirm health, compunction for her conduct in early life towards her father, and an aversion to bloodshed, all concurred to make her desire to close her reign in peace. She regarded, and with reason, Marlborough's conduct in the late negociations, as one of the principal obstacles to a termination of hostility. The public relieved from apprehension, and seeing no British interest at stake, was no longer solicitous to prolong a contest by which Austria was to be a chief gainer. The Dutch were actuated by similar feelings, but their leading men continued to be influenced by Marlborough. The latter went every advisable length in opposition to the change of ministry, and finding, at last, that he could not prevent it, made, like a true politician, a merit of necessity, and declared that he would henceforth interfere no more in her majesty's civil affairs, but confine his services to his profession. The weight of his reputation obliged the new ministry to keep him in the command more than a twelvemonth after the fall of his political adherents; and it was not until the end of 1711, that they ventured to deprive him of his employments. This took place after bringing forward certain charges of appropriating to his own use, funds belonging, as they said, to the public. The specific charge consisted in the acceptance, on the part of the duke, of L. 5000 sterling a year, from the contractor for army bread. The duke explained that this and other payments formed a regular allowance to the commander in chief, who, in return, took on himself the whole expence of the secret service. King William, he added, had received in great part those allowances for which he was now censured. Though the Duke's defence is, according to our present notion of a general's honour, unsatisfactory, the wonder is that, with such opportunity as he possessed, and such a fondness for money as has been imputed to him, his enemies should not have discovered much weightier charges against him.

The accusation, such as it was, having produced considerable effect on the public mind, ministers ventured to transfer the command of the forces to a different general. It was in vain that the allies intreated them to let the Duke keep his command, and that Prince Eugene came over to London to endeavour to recall the queen to cordiality in the war. All would not do, and the prince had no other satisfaction than that of shewing, that change of fortune made no alteration in his behaviour towards his illustrious associate in arms. Policy, it is said, in his *Memoirs*, would have dictated a different course—the way to succeed with the queen and her new ministers, would have been to shun and decry Marlborough; but "I threw myself," says the prince, "with rapture into his arms, and the English nation, nay Marlborough's own enemies, must have esteemed me the more for it." The campaign of 1712 soon shewed what the allied cause had lost by the change of a general. The Duke of Ormond was no Marlborough, and he was, moreover, restricted from co operating offensively with the allies. This, and the too hazardous conduct of Prince Eugene, led to the check at Denain, which furnished matter of great exaltation to Villars, and led to a turn of the war in favour of the French. It is needless to add how miserably our affairs were managed at the treaty of Utrecht.

During the year 1712, the Duke of Marlborough remained as a private individual in England. Towards the end of the year he took the determination to go abroad. His course was by Ostend and Antwerp to Aix-la-Chapelle, at each of which places he was received with distinguished honour. He thence proceeded to visit the estate in Suabia, given him by the emperor of Germany, and afterwards passed some time at Hanover. His return to England happened to take place in 1714 at the time of the queen's death. On the accession of

George I. he was restored to all his honours, and declared captain general and commander in chief of our land forces. In this capacity he was not long able to act an efficient part, for age and care had impaired both his mind and body. Soon after giving directions for checking the rebellion in 1715, he retired from public business, and passed his remaining years in the country. The decay of his faculties afforded, it is said, an affecting spectacle, when viewed in contrast with his former splendour. His death took place at Windsor lodge in 1722, in his 73d year. He left no son, but four daughters, and his title has descended to the posterity of his second daughter.

It remains that we say a few words on a part of the Duke's conduct which has been much animadverted upon,—we mean his behaviour to the Stuart family. It appears, from "M'Pherson's State Papers," that he continued to give them hopes of a friendly disposition on his part, after he was evidently connected with the house of Hanover. M'Pherson, it is manifest, was not partial to the Duke's memory, nor slow in bringing forward whatever could constitute a charge against him. At the same time, it would be contrary to historic fidelity to represent the Duke as much fairer than the majority of those who pass their life in courts and cabinets. He would have sided, in all probability, with either Hanover or Stuart, as best suited his political views, and might have leaned decidedly to the latter, had there been any hope of their conforming to the Protestant religion. Those who accuse him of unbounded avarice will do well to recollect, that all the temptations of this nature, offered to him by the French court at the conferences of Gertruydenburg, were completely unavailing. (x)

CHURCHILL, Charles, was born in Vine-street, in the parish of St John the Evangelist, Westminster, in February 1731. His father was for many years curate and lecturer of that parish, and rector of Rainham near Grays, in Essex. Young Churchill was placed at Westminster school at eight years of age, and, in his 19th year, applied for matriculation at Oxford, but was rejected, either from inability to answer the questions that were put to him on his examination, or from a petulant contempt of his examiners, which was mistaken for ignorance. He was afterwards admitted to Cambridge; but instead of revisiting the university, he made a clandestine marriage in London, after the discovery of which, his father took home the imprudent couple to his own house for a twelvemonth. Young Churchill now applied in earnest to such studies as might fit him for the church. At the customary age he received deacon's orders, and in 1756 was ordained a priest. He first preached at Cadbury in Somersetshire, and at Rainham his father's living. At the latter place, he endeavoured to provide for his family by teaching the youth in the neighbourhood; but in 1758, his father's death opened a new prospect to him in the metropolis, where he was chosen his successor in the curacy and lectureship of St John's. For some time he performed his duty in these offices with external decency, and added to his income by private tuition; but about his 27th year he began to relax from habits of industry and decorum, and to plunge into debt and dissipation. The father of his friend, Lloyd the poet, one of the masters of Westminster, persuaded his creditors to accept of five shillings in the pound, and to grant him a release. Amid all the profligacy of Churchill's life, it deserves to be told, that when he had afterwards realised some money by his writings, he voluntarily paid the full amount of his debts. After several poetical efforts, which were either suppressed by advice of his friends, rejected by the booksellers, or which attracted but insignificant notice in a magazine, his attendance at the theatres suggested a subject of satire against a set of men, who have seldom any means of retaliation. The Rosciad appeared in 1761, and its success, together with that of its sequel the Apology, a severe satire on the reviewers who had attacked it, was such as to produce at once fame and profits, and to open new prospects to his ambition. Unhappily the decline of his moral conduct kept pace with the rise of his literary name. His profligacy drew down the displeasure of the dean of Westminster, and had long shocked his parishioners. Churchill conceiving his dignity above reproof, and probably feeling his habits beyond the power of reformation, threw off his clerical character, and with that the few restraints of external decency which it yet imposed. He dressed his uncouth form in a splendid fashionable suit, parted from his wife, and addressed a poem, entitled Night, to his friend Lloyd, which is little more than a doleful exhortation not to blush for immorality. His next publication was the Ghost in 1762, founded on the Cock lane story, but which he contrived to make the vehicle of some characteristic sketches. His acquaintance with Wilkes commenced about this time, and he probably wrote in the North Briton. For this political patron, his Prophecy of Famine was contrived,—a piece, which has strong though scurrilous humour, and was admirably fitted to raise the horse laugh of party and nationality. The Epistle to Hogarth, his next poetical production, was much more personal, and, from its personality, more malignant. Whatever was the cause of the quarrel, and it is by no means certain whether Hogarth's caricature of the Bear and the Mug of Porter (in allusion to Churchill's fondness for that beverage) preceded or followed the poet's angry epistle, it is disgusting to peruse his reproaches of the painter for being old and infirm.

In 1763, Churchill seduced the daughter of a tradesman in Westminster, but, after a fortnight's cohabitation, they were seized either with satiety or repentance, and her father was persuaded to take her back. Her home, however, being made intolerable to her by the ill nature of a sister, Churchill thought himself bound in honour to renew the connexion. While the subject was public, he wrote the Conference, a piece full of penitence and expressions of grief. In the same year, the duel between Wilkes and Martin gave occasion to his poem entitled the Duellist. His *Author*, an inconsiderable effusion, appeared during the same year. His Gothham, published in 1764, has a few strong lines, but is heavy, and without a distinct object or plan. The Candidate was written against Lord Sandwich, when he competed for the stewardship of the university of Cambridge. Churchill, with great impartiality, attacks his Lordship for the same vices which distinguished himself. The two last pieces published in his lifetime, viz. the Times, and Independence, added little to his reputation. Towards the end of October, he accompanied Mr Cotes, one of Wilkes's partizans, on a visit to the exiled demagogue in France. The party met at Boulogne, where Churchill was attacked with a fever, that terminated his life in his 34th year. If his will is to be credited, he left money at his death. On his tomb was written, "Life to the last enjoyed, here Churchill lies."

Churchill died at that early age, when most men are only beginning to distinguish themselves, and his genius certainly contained the seeds of greater excellence than it ever brought to maturity. The poetical character which he did attain, is that of a bold, courageous, but slovenly artist. He has more of the vehemence of Dryden than any other English satirist, but none of that majesty of thought, that pomp of diction, or harmony of numbers, which give the hostility of Dryden in satire the dignity of moral warfare. Cowper gives his character with considerable indulgence, but with some truth, in a passage to his memory. The reader will perhaps need but little criticism to perceive, that there is a confusion of metaphors in Cowper's lines that we allude to, when the poet is first compared to a rider, and, in the next line, placed at his lyre.

> Surly and slovenly, and bold and coarse,
> Too proud for art, and trusting in mere force;
> Spendthrift alike of money and of wit,
> Always at speed, and never drawing bit.
> He struck his lyre in such a careless mood,
> And so disdained the rules he understood—
> The laurel seemed to wait on his command:
> He snatched it rudely from the muse's hand.

CIBBER, Colley, an eminent actor and dramatic writer, was born in London on the 6th of November 1671, O. S. His father Gabriel Cibber, who was a statuary by profession, came from Holstein to England a little before the restoration, and immortalised himself by the two famous images of raving and melancholy Madness, placed on the piers of the great gate of Bethlehem hospital, and by the basso relievo upon the pedestal of the Monument.

Young Cibber was sent to the free school of Grantham in Lincolnshire at the age of 11, and, after remaining there seven years, he stood a candidate for admission into Westminster college. Being disappointed in these views, he was anxious to be sent to one of the English universities, to be educated for the church; but his father having taken an active part under the Earl of Devonshire in the cause of the Prince of Orange, young Cibber repaired to the same standard, and continued for some time to practise the duties of a soldier.

As soon as he received his discharge, he became remarkably fond of theatrical exhibitions, and, in the year 1689, he came upon the stage for a weekly salary of ten shillings. Neither his person nor his voice seemed well fitted for any great dramatic effort, and he was accordingly employed for a considerable time in the lowest characters. When Queen Mary, however, ordered Congreve's *Double Dealer* to be acted, Mr Kynastown, who originally played the part of Lord Touchwood, was taken suddenly ill, and upon the recommendation of Congreve, Cibber undertook the character at a very short notice. The ability with which Cibber performed his part, gained him the particular applause of Congreve, who recommended him to an increase of salary from 15s. to 20s. per week. About this time, his father settled upon him an annuity of £20 a year; and in 1693 he married a Miss Shore, of whose beauty and accomplishments he had been very suddenly enamoured.

On the opening of Drury-lane theatre in 1695, he wrote an original prologue, which was admitted as the best that had been offered; but so low was his reputation as an actor, that it was accepted solely on the condition, that he should relinquish any claim to recite it himself.

Cibber gained great fame by his performance of Fondlewife, in the Old Bachelor, where he imitated Dogget, the original performer of the part, in the happiest and closest manner; and his name was raised still higher by his first dramatic production, called *Love's Last Shift*, or the *Fool of Fashion*, which appeared in 1696, and which Lord Dorset, who was then lord chamberlain, pronounced to be the best play he had ever read. From this time Cibber rose with rapidity in the public estimation. His *Woman's Wit*, which appeared in 1697, was however ill received. His *Xerxes*, which was brought out in 1699, was acted only one night; and his *Careless Husband*, which appeared in 1704, though by no means a perfect play, has been much admired, and is reckoned his principal comedy.

In 1711, Cibber became joint manager and patentee of Drury-lane Theatre, along with Collier, Wilkes, and Dogget; and, in 1717, he brought forward his comedy of the *Nonjurors*, which, being levelled against the jacobite party, was acted for eighteen successive nights, and obtained for him from the king L. 200, and the office of poet-laureat. In 1740, he published *An Apology for the Life of Mr Colley Cibber, Comedian, with an Historical View of the Stage during his own time:* a very lively and entertaining work. In 1745, when he was in his seventy-fifth year, he acted with great spirit the character of Pandulph, the pope's legate, in the new tragedy written by himself, and entitled *Papal Tyranny in the Reign of King John.* The last of Cibber's literary labours, was a work entitled *Remarks on Middleton's Life of Cicero*, which was published in 1747, and which added nothing to his fame. Worn out with years, Cibber died suddenly on the 12th December 1757, in the eighty-seventh year of his age. His man-servant had talked with him at 6 o'clock in the morning, when he apparently enjoyed his usual health; but, at 9 o'clock, he found he had expired, in the same position in which he had left him. Cibber left behind him a son and a daughter, both of whom disgraced the memory of their father.

In his dramatic character, Cibber has drawn a very faithful picture of himself, which we shall give in his own words: "I was vain enough to think," says he, "that I had more ways than one to come at applause, and that, in the variety of characters I acted, the chances to win it were the strongest on my side. That if the multitude were not in a roar to see me in Cardinal Wolsey, I would be sure of them in Alderman Fondlewife. If they hated me in Iago, in Sir Fopling they took me for a fine gentleman. If they were silent in Syphax, no Italian eunuch was more applauded than I when I sung in Sir Courtly. If the morals of Æsop were too grave for them, Justice Shallow was as simple and as merry an old rake as the wisest of our young ones could wish me; and, though the terror and detestation raised by King Richard might be too severe a delight for them, yet the more gentle and modern vanities of a Poet Bayes, or the well bred vices of a Lord Fopling, were not at all more than their merry hearts or nicer morals could bear."

Besides his two Letters to Pope, his Apology for his own Life, and his Remarks on Middleton's Life of Cicero, Cibber wrote the following dramatic pieces: 1. *Love's last Shift*, 1697; 2. *Woman's Wit*, 1697; 3. *Xerxes*, 1699; 4. *Love makes a Man*, 1700; 5. *King Richard the Third*, 1700; 6. *She would, and she would not*, 1703; 7. *Careless Husband*, 1704; 8. *Perolla and Izidora*, 1706; 9. *Schoolboy*, 1707; 10. *Comical Lovers*, 1707; 11. *Double Gallant*, 1707; 12. *Lady's last Stake*, 1708; 13. *Rival Fools*, 1709; 14. *Venus and Adonis*, 1715; 15. *Myrtillo*, 1715; 16. *Nonjuror*, 1718; 17. *Ximena*, 1719; 18. *Refusal*, 1720; 19. *Hob, or the Country Wake*, 1720; 20. *Cæsar in Egypt*, 1725; 21.

Provoked Husband, 1727; 22. *Rival Queens*, 1729; 23. *Love in a Riddle*, 1729; 24. *Damon and Phillida*, 1729; 25. *Papal Tyranny in the Reign of King John*, 1745. (*j*)

CICERO, Marcus Tullius, born in the 647th year of Rome, was descended from an ancient and honourable family, which had been of equestrian rank since the time of its first admission to the freedom of the city. He was, indeed, called at one time a *Novus homo*, but only because he was the first of his family who sought and obtained public magistracies. His birth-place was Arpinum, now part of the kingdom of Naples. The family seat was about three miles from the town of Arpinum, and is described in one of Cicero's letters as exceedingly beautiful, being surrounded with groves and shady walks leading from the house to the river Fibrenus, which was divided into two equal streams by a little island covered with trees. Here stood a portico, contrived both for study and exercise, to which Cicero retired for meditation. A clear and rapid stream, shaded with poplars, murmured through a rocky channel, and fell a little below the island into the noble river Liris, in a cascade. This place, consecrated by the memory of Cicero, was lately inhabited by a convent of monks, and was called the Villa of St Dominic.

Cicero's first name, corresponding to our baptismal name, was Marcus, after his father: Tullius was the family name, signifying a flowing stream, probably from the conflux of waters on their grounds: Cicero, the other family name, is ascribed by Pliny to the reputation of his forefathers for the cultivation of vetches. His early education was, according to the Roman custom, committed to a discreet matron; but when of age to be placed at a public school, he was brought to Rome, where his father had a house. There, we are told by Plutarch, he was so distinguished, that his school-fellows attended him in a body to and from school, giving him the place of honour among them, and that parents often visited the school to see so extraordinary a youth. Among the instructors of his youth was the poet Archias. Under him he applied chiefly to poetry, though with what small success is proverbially known. This circumstance, however, shews the universality of his taste, if not of his talents. Indeed, it is observable, that few geniuses which have ever swayed mankind by eloquence, from Cicero to Chatham and Fox, have left their love of poetry unrecorded in some effort to compose it. On assuming the manly dress, he was introduced into the forum, under the care of Quintus Curtius Scævola, the principal lawyer of the age. The peace of Rome being soon after disturbed by the Italic or Marsic war, the forum was, as usual, deserted, and the orators repaired to fight at the head of their military divisions. Cicero went out as a tiro under Pompeius, Strabo, and Sylla. Returning to Rome, he resumed his philosophical studies under Philo, chief of the academy. Molo, an eminent pleader and master of rhetoric, was his next teacher. Amidst these studies he published some remarks on Rhetorical Invention, translated Xenophon's Œconomics, and versified the Phænomena of Aratus. But his taste both in poetry and rhetoric seem, at this time, to have been rude and imperfect.

At the age of six-and-twenty, our orator pleaded his first cause with equal honour to his eloquence, his humanity, and intrepidity. Rome was now under Sylla, whose proscriptions had silenced all laws. A citizen, Roscius Amerinus, had been stript of his inheritance by two of his relations, who had assassinated his father, though he was not in the list of the proscribed, and fearing that the son might reclaim his property, charged him with the murder which they had themselves committed. They were supported in this accusation by one who had participated in the booty, Chrysogonus the freedman of Sylla. Not another advocate at Rome would expose himself to the terrible resentment of such antagonists, when Cicero, with youthful boldness, undertook to defend the innocence of Roscius, and gained his cause. His address in this business was very conspicuous; for while he attacked the freedman of Sylla with indignation, he pretended to consider Chrysogonus's conduct as unknown to Sylla, and unwarranted by his authority. He remained in Rome a year after this event, engaged in the business of pleading, and in one cause exposed himself still more openly to the danger of the tyrant's resentment. In the cause of a woman of Arretium, he defended the rights of certain towns in Italy to the freedom of Rome, which Sylla had taken away, and gained his plea, though opposed by the distinguished orator Cotta.

He was 28 years old when he set out on his travels. At Athens he studied Greek philosophy with that deep curiosity and discrimination which has enabled him to be the most faithful reporter of its outlines; and here, as well as at Rhodes and in Asia, he mingled the study of oratory with that of philosophy. At the end of two years he returned with his lungs repaired, his constitution confirmed, and the solid faculties of his mind polished to their utmost brilliance. At this time the greatest of the Roman orators were Cotta and Hortensius. The former was a decided mannerist, and so remarkable for a swinging action, that it was satirically said he had learnt his eloquence in a boat. Hortensius had been hitherto called the king of the Roman bar, but his crown was soon to be transferred to Cicero. Our orator, however, did not think himself yet entirely accomplished in the exterior requisites of a speaker, but took lessons from the eminent players, Æsopus and Roscius, the latter of whom he successfully defended in a pecuniary cause.

In his 31st year, he was chosen one of the questors. These officers, who were sent annually into the provinces as assistants to, or rather as checks upon, the proconsuls or governors, had the care of the provincial revenues, of providing grain for the armies abroad, and the public consumption at home. The office was the first step in the ascent from plebeian to patrician dignity, as from the questors who had been censors, the vacancies of the senate were supplied. The marriage of Cicero probably took place in the same year. He was appointed to the questorship of Sicily, and filled it so as for ever after to possess the gratitude of the Sicilians. We shall presently have occasion to observe how very rarely the provinces had the good fortune to have a Cicero among them. Before he left Sicily, he made the tour of the island. At Syracuse, he enquired of the magistrates if they could point out to him the tomb of Archimedes. It marks the degradation of a conquered people, that they knew not the spot where the dust of their greatest genius reposed. But Cicero discovered it. When they had carried him to the gate where the greatest number of their old sepulchres stood, he observed, in a place overgrown with shrubs and briars, a small column, of which the head just appeared above the bushes, with the figure of a sphere and a cylinder engraved. On clearing the ground, he found also (though mutilated) the inscription which he expected:

So Tully paus'd, amid the wrecks of time,
On the rude stone, to trace the truth sublime;
When at his feet, in honour'd dust disclosed,
Th' immortal sage of Syracuse reposed.—ROGERS.

After his year of questorship, he returned to the Roman bar, and was elected ædile by the universal suffrages of the tribes. The ædiles were police magistrates, whose duty was to take care of the public buildings, to inspect the markets, weights and measures, and to regulate the shows and public festivals. At this period, in the strength of his powers, and progress of his honours, he was called upon by the Sicilians to accuse Verres, their base and violent oppressor. Verres, guilty as he was, had the support of the powerful at Rome. The great men, who regarded it as one of the rights of office to fleece the provinces assigned to their charge, made common cause with him, and used every means to disarm the laws. Cicero demanded three months and a half to go to Sicily, and collect proofs against the culprit; but aware that it was in view to postpone the trial till next year, when the friends of Verres were expected to be the prætor and consuls, he collected his facts in 50 days, brought his evidence to Rome like a thunderbolt on the accused, and *by one speech*, in which he produced witnesses of every fact, confounded his adversary Hortensius, and raised such a storm of indignation against Verres, that he was advised not to wait for judgment, but to betake himself to exile. The lenity of Roman law did not seek for farther vengeance on a Roman citizen, when he went voluntarily into banishment. Verres, whose crimes deserved an hundred deaths, fell afterwards a victim to Octavius and Anthony. Having refused to the latter some Corinthian vases and Greek statues, of which he had plundered the Sicilians, he was proscribed; and Verres and Cicero died by the same persecution.

On this occasion, the only one, as Cicero boasted, in which he had hitherto appeared as an accuser, he pronounced only two orations, but left five others as models of the style in which an accusation should be supported in all its parts. The two last of his Verrine orations are regarded as the masterpieces. The object of one of them is to expose the rapine and injustice of Verres, the other his more wanton barbarities. The first is remarkable for the variety and richness of its detail, the interest and picturesqueness of its narrative, and, above all, by the art which he employs to prevent satiety in a series of robberies; the other is still more admirable for its vehemence and pathos. It displays all the resources which the orator can bring, to work upon the hearts of his audience, and to excite their moral indignation. A frightful picture, indeed, those speeches exhibit of the Roman governors in their arbitrary use of "brief authority," and a full display of the desolate corruption which had grown over the stagnated justice of Roman law.* At the time that Verres was entrusted with the prætorship of Sicily, its sea-coasts were infested by pirates, and though the prætor's duty was to support a fleet for the protection of commerce, he employed that trust only as the means of new exactions. Obliging the soldiers and sailors to purchase immunity for their services on board the defensive fleet, he manned it so imperfectly, or rather so totally dismantled it, that it was wholly unfit for service. At the head of this miserable squadron he put not a Roman, as he was bound to do by law, but a Sicilian, Cleomenes, whose wife was the prætor's mistress. At the first sight of the pirates, the Roman fleet took to flight, Cleomenes setting the example. The pirates burnt their deserted ships, and entered Syracuse in triumph. This disgrace to the Roman arms made considerable uproar at Rome. It was notorious, that the captains of the galleys had acted from necessity, as they had only followed their admiral in vessels which could not have fought the pirates. Yet Verres brought those innocent men loaded with irons to imprisonment and trial. Cleomenes was alone excepted from accusation, though he had fled first. On the contrary, he took his seat at the side of the prætor, and was seen as usual familiarly talking with him. The men of the most respectable birth and character in Sicily, when they pleaded their cause, were threatened with death if they uttered the name of Cleomenes, and, when they alluded to the true causes of their retreat, were struck over the eyes, at the command of Verres, by the lictors. When the dreadful sentence was passed, its horrors were even extended to their relatives. Parents, says the orator, were interdicted the sight of their children; they durst not bring them clothing or food. Stretched before the thresholds of their prisons, there did miserable mothers pass the night in tears, without being able to obtain a last embrace of their sons. There they sought as a favour to breathe the last sighs of the condemned, but they sought it in vain. It was there, that the barbarous servant of Verres, the lictor Sergius, the terror of the citizens, established a revenue from the agonies and tears of the unfortunate. So much he asked for leave to visit your child; so much to give him food. Nobody refused it. What will you give me to make your son die by one blow, that he shall not suffer protracted pain? Horrible trade of tyranny, when life was not sold as a favour, but the promptitude of death itself. But does the outrage on humanity stop here, or can barbarity itself go farther? Yes, says the tyrant, when they have been executed, their bodies shall be exposed to beasts of prey; and the parents of the unfortunate must purchase a privilege to bury them. Such were some of the facts, all substantiated by evidence, which Cicero charged against this culprit with strong and pathetic eloquence. When he comes to the particular case of Gavius, he exhibits a most minute and strong case of oppression, which makes even at this day the reader's blood boil with indignation; but must have roused still stronger sensations in the bosoms of his audience, as he appealed to a principle, which was absolutely religious in the Roman mind, namely the respect which was maintained for the name of a Roman citizen. Is it lawful, said St Paul, to scourge a Roman? That sacred title the greatest power durst not violate with impunity; and the republic was ready to carry war to the utmost corner of the world, to avenge an outrage committed on a single citizen,—a sublime principle, which imposed respect for the Roman name on the fiercest barbarians, while it taught the people themselves to love its value. In the case of

---

* There was not a considerable estate in Sicily disposed of by will, where Verres had not his emissaries at work to find some flaw in the title, or some omission in executing the conditions of the testator, as a ground of extorting money from the heir. The tenths of the corn in all the conquered towns of Sicily belonged to the Romans, as it had formerly belonged to their own princes. By an outrageous edict respecting those tithes, Verres threw the property of the whole island into the power of his officers, to whom he farmed the taxes, who seized the whole crops, and obliged the owners to compound at mercy for what was left to them. From the registers that were kept in every town, it appeared, that during three years of Verres's government, above two-thirds of all the farmers had deserted their farms, and left their lands uncultivated. Montesquieu tells us of savages in Louisiana, who cut down the tree in order to get the fruit. Behold, says he, an emblem of despotic policy!

Gavius, where Verres had violated this law, the genius of the orator seems to expand with the horrible richness of his subject, and he surpasses himself in eloquence, as much as Verres surpasses the ordinary limits of human cruelty.

Cicero passed from this accusation to fulfil the duties of his office as curule-ædile. The people were passionately fond of public festivals, and it belonged to that office to supply the greater part of those at his own expence, the public allowance for them being small, according to the frugality of the old Roman republic. It was dangerous to be frugal on such occasions, as Mamercus had lost the consulship by declining the ædileship; yet Cicero avoided the opposite extreme of prodigality, by which Cæsar had ruined his fortune. The Sicilians, during his ædileship, gave him effectual proofs of their gratitude, by supplying him largely with all kinds of provisions which their island afforded, for the use of his table and the public feasts; but, instead of making any private advantage of their liberality, he applied the whole to the benefit of the poor, and augmented his popularity by reducing the price of the markets.

His private affairs, in the mean time, though not flourishing, were kept, by good management, in a respectable condition. He had married Terentia, a woman of family, whose fortune added to his own patrimony, enabled him to purchase a house on the Palatine Hill in Rome, and keep up a handsome villa at Arpinum. As there was no honour in the state to which he might not pretend, he was careful to cultivate the favour of the people; and, at the same time, it must be owned, that, amidst a general disposition to patriotism, he kept the favour of the powerful by accommodations, which, in rigid virtue, cannot be defended. Pompey was aiming at power beyond the limits of the constitution; yet the necessity which he found for that great man's support, made him subservient to his views of ambition. In his fortieth year, Cicero was nominated to the prætorship: he entered his office on the ensuing year, and presided over the courts of justice with great integrity. But the famous oration which he made in favour of the Manilian law, which conferred almost sovereign powers upon Pompey, though one of the noblest monuments of his eloquence, can only be considered as an interested piece of policy, to ingratiate himself at once with Pompey and Cæsar: the former of whom desired the dangerous power which the Manilian law conferred upon him for the sake of its immediate use; the other wished Pompey to obtain it, most probably that he might establish a precedent for enormous military commissions, which his conscious genius foretold him that he should one day possess.

Cicero had now the consulate in full view. On the expiration of his prætorship, he therefore refused to accept of a province. The consular election took place in his forty-third year. But to pass, for a moment, from the view of his public to his private life, from the statesman to the scholar, it is interesting to find him, at this busiest period of his life, as eager in the pursuit of books, and fine specimens of art, as if his time and fortune had been unoccupied by other objects. In his beautiful retreat at Tusculum, he had constructed rooms and galleries in imitation of the schools and porticos of Athens, which he called by their Attic names of the Academy and Gymnasium, and designed for the conferences of his learned friends. He had given Atticus a general commission, to purchase for him any piece of Grecian art or sculpture which was elegant and curious: a commission which Atticus executed to his great satisfaction, and sent him, at different times, several cargoes of statues. So intent was Cicero on embellishing his Tusculan Villa, that he sent over to Atticus the plans of his ceilings, which were of stucco-work, in order to bespeak pieces of sculpture or painting to be inserted in the compartments. Nor was he less intent on forming a Greek library by the same help. Atticus was remarkable, above all men in his rank, for a family of learned slaves, having scarce a footboy in his house who could not both read and write for him. For those copies, however, it appears that Atticus had demanded a sum which the other was yet unable to raise. "Pray, keep your books for me," says Cicero, in one of his letters to Atticus, "and do not despair of my being able to make them mine; which, if I can compass, I shall think myself richer than Crassus, and despise the fine villas and gardens of them all." In another letter he continues, "I am setting apart all my little rents to purchase that relief (a collection of books) for my old age." In a third letter he says, "that he placed all his hopes of comfort and pleasure, whenever he should retire from business, on Atticus preserving his library for him."

It was greatly to the honour of Cicero, that one of the motives for electing him to the consulship, was the general fear which prevailed of an impending conspiracy. When chosen to that high office, in his forty-fourth year, he found the public tranquillity endangered from several causes. The sons of those who had been proscribed by Sylla, were brought forward by the tribunes as candidates for public offices. An Agrarian law, a measure at all times full of hazard, was proposed by the tribune Rullus. The law of Otho, for appropriating separate seats in the theatre to the equestrian order, occasioned several popular tumults. Above all, the designs of Catiline were aimed at the vital principles of peace and social order. The colleague of Cicero, *Antonius*, was quite incapable of co-operating with him, either by capacity or virtue. Cicero, therefore, judiciously contrived to get rid of him, by persuading him to accept of the province of Macedon, which he had himself obtained by lot. His eloquence and influence were next employed, in opposing the scheme of the demagogue Rullus for an Agrarian law, to be enforced by a decemvirate of commissioners, who were to have absolute power for five years over all the revenues of the republic; to require an account from all generals of spoils taken abroad; to settle colonies; distribute, buy, and sell land, and judge of the rights of proprietors at pleasure; and, in short, to command all the money and forces of the empire. In this business, Cicero repeatedly challenged the tribunes to come face to face, and dispute with him. They were forced at last to submit to him.

The detail of the Catilinarian conspiracy belongs to a different place in our work. It is sufficient to say, that, after he obtained a clue which made him master of all the labyrinth of that wretch's plans, he obtained a decree of the senate, ordering the consuls to take care lest the republic should receive any detriment. By those few and pithy words, they were invested with almost dictatorial power. Cicero delegated the charge of foreign affairs to Q. Metellus, reserving to himself that of the city. Accompanied by a large body of friends, and armed with a breast-plate, he descended into the Campus Martius, where the conspirators, not daring to move Catiline again, underwent a repulse. Thus rendered desperate, the incendiary summoned his party by night, and fixed upon a day for setting fire to the city, massacring the chief senators, and seizing the capitol. In the mean time, he had engaged two Roman knights to as-

assassinate Cicero in his own house; but the consul being acquainted with all his designs, refused admission to the assassins.

This was the state of the conspiracy, when Cicero delivered the first of those four speeches that were delivered upon the occasion of it, and are still extant. The senate had been summoned to the temple of Jupiter in the capitol, where it was not usually held, but in times of public alarm. The audacious appearance of the traitor in this place, drew down that memorable burst of the orator's eloquence, in which he indignantly denounced to Catiline the discovery of his treasons, and the certainty of his punishments; and, after detailing to the senate whatever had been done at the meetings of the conspiracies, pressed Catiline to quit the city, telling him that the gates lay open, and that nobody should prevent his departure. This terrible oration was the first punishment which Catiline suffered, by his folly in going to the senate. Yet neither the voice of Cicero, nor of his own conscience, could entirely deprive him of the courage to attempt a reply. But though the law forbade any senator being interrupted, he had scarcely pronounced a few vague phrases, when murmurs began on all sides, which speedily swelled into a cry of indignation, and the names of parracide and incendiary were rung in his ears.

Finding it impossible any longer to wear the masque, he rushed out of the senate, vowing, " that he would extinguish, under the ruins of his enemies, the fire which they were lighting around him."

The event justified Cicero's political sagacity: Catiline, the following night, went out of Rome with 300 desperadoes, and put himself at the head of the troops of Mallius. The issue of his bloody struggle with the troops of the republic is well known. After a vain attempt to push his escape over the Appennines into Gaul, his miserable army engaged with the forces of Petreius, and were cut off to a man.

After Catiline's departure, Cicero mounted the rostra, and, in his second Catilinarian oration, gave the people an account of all that had passed. His object was, to dissipate the false alarms which the conspirators insidiously spread, exaggerating their own resources, and the danger of the republic: he proved, that it was only in Rome that Catiline could strike a blow, and, being driven from thence, that he was for ever lost. The imprudence of the conspirators who were left behind by Catiline, precipitated their destruction, even before the death of Catiline himself. Cicero detected Cethegus, Lentulus, and others of them, in treasonable correspondence with the ambassadors of the Allobroges, produced their letters in the senate, and on the clearest evidence, and even on their own confession of guilt, obtained a decree of the senate for putting them to death. Thus ended a conspiracy, in which some of the most powerful men in Rome were suspected of having been implicated, though its principles, and its avowed agents, were the most abandoned and atrocious. While the recollection of Cicero's services was fresh in the public memory, all orders of society joined in the most grateful applause, and perhaps no man ever enjoyed a more enviable triumph. Catalus, in the full senate, declared him the father of his country; and Cato repeated it from the rostra, with the loudest acclamations of the people. This glorious title, the imperial tyrants of Rome were proud to extort from slaves and flatterers, which Cicero obtained from the free vote of the senate and the people.

When Cicero's consulship was concluded, he resigned it, according to custom, in a full assembly of the people. This ceremony was generally accompanied with a speech from the expiring consular; and, from such a speaker as Cicero, an interesting address was naturally expected. Metellus, one of the new tribunes, invidiously determined to disappoint both the orator and the people; and when Cicero had mounted the rostra, declared that he would not suffer him to speak. On which Cicero, who was never at a loss, instead of pronouncing the ordinary form of the oath, raising the tone of his voice, swore so loud that all the people could hear him, " that he had saved the republic and the city from ruin;" which the multitude below confirmed with an universal shout, crying out, " that it was true."

——— *Roma parentem*
Roma patrem patriæ Ciceronem libera *dixit.*

From the time of his consulate, Cicero's influence in Rome began to decline. The rising popularity of Cæsar, the triumphal return of Pompey from Asia, and his reconciliation with Crassus, which laid the foundation of the first triumvirate, occupied the minds of men, and confined the stream of power to a particular channel. Cicero employed himself chiefly in literary and forensic pursuits. He composed the history of his consulate in Greek, for his friends Atticus and Possidonius, and he made the same theme the subject of three books of verse. He defended several considerable causes; and thus endeavoured, by conferring new obligations, to compensate the loss of former favours. He was, indeed, sensible that a storm was gathering against him. He had incurred the hatred of the violent, and abandoned Publius Clodius, by appearing as an evidence against him, when prosecuted for violating the mysteries of the *Bona Dea*. Clodius, who was resolved upon his ruin, had, by means of a plebeian adoption, made himself eligible to the tribuneship of the people; and, as he was a political tool of the triumvirate, he was supported by Cæsar and Pompey, though they assured Cicero that there was no intention of injuring him. Clodius, however, as soon as he was made tribune, began his attack, by proposing a law, that whoever had been concerned in the death of a Roman citizen should be deemed guilty of treason against the state. This was so obviously aimed against Cicero, that he immediately assumed the habit of a mourner, and went about soliciting the protection of his friends. Such was the regard he still inspired, that the whole order of knights went into mourning, and joined in his supplications; and young Crassus, the son of the triumvir, who had been his pupil in eloquence, attended upon him with a large body of the Roman youth, in order to defend him from the violence of Clodius and his mob. His counsels were now perplexed by the different opinions of his friends. The question was, whether he should remain in Rome, and defend himself by force, or save the effusion of blood, by retreating till the storm should blow over. Cato advised him to the latter plan: It is unfair, as many have done, to impute his inclination to this advice to timidity; for no man seems to have felt the pain of exile more deeply than Cicero, although the fears and intreaties of his family might operate on his resolution. He therefore applied to Cæsar, to take him as his lieutenant into Gaul. The artifices of Clodius, who pretended to wish for a reconciliation, induced him to change his purpose, and decline accepting; by which he offended that commander, or, perhaps, rather afforded him a pretext for sharing in the base desertion of him; which Pompey, with still less excuse, did not blush to be guilty of. Clodius, then, directly impeached him for having put to death Lentulus, Cethegus, and the rest of Catiline's associates, without a legal trial. Thus abandoned, the father of his country went voluntarily into banishment, and Rome suffered sentence of interdiction from fire and water to be passed against him; though the friends of liberty still secretly shed tears, and put up prayers for his welfare. In his 49th year, the fifth from the time of his consulate, he wandered desponding over the south of Italy, and finally settled in Greece. The melancholy which his letters express during this sad period of his existence, have drawn upon him the censure of weakness; and they certainly discover him to have been no Stoic: but much allowance should be made for a mind exquisite in its texture, though great in its compass,—for sensibility, flushed and warm with recent glory,—for genius, torn from the community which it had saved and adorned.

His enemy, Clodius, who was now the pest and fury of the republic, had, however, but a temporary triumph over one who was loved by the great body of the people. He burnt Cicero's villas, and house on the Palatine, and confiscated his effects; but when the estates were brought to auction, none would bid for them. Pompey himself began to be ashamed of having deserted him, and, being irritated at Clodius for some instances of insolence which came nearer his own dignity, joined with the party who planned his recal. A decree for that purpose was at first successfully resisted by the tribune Clodius, who, in defiance of the senate, absolutely slaughtered the partizans of Cicero in the forum. But the senate at last carried their point. The citizens of the towns of Italy flocked to Rome from all quarters to support their authority. The news of the favourable decree was received at the theatres with acclamations and tears of joy. Æsopus, the tragedian, when acting on the stage a part in which he invoked the name of Brutus, substituted Tullius in its place, and the people were so affected that they called for it over and over again. A meeting of the tribes was held in the field of Mars, and the law of the senate was confirmed by the unanimous suffrages of all the centuries. This was one of the last acts of Roman liberty. The day of the patriot's return to Brundusium, happened to be the annual festival of the foundation of the town, and the birth-day of his daughter Tullia, who came to that place to meet him. The fame of his landing and progress to Rome, drew multitudes from all parts, so that the whole road from Brundusium to Rome was one crowded and continued street; nor was there a prefecture, town, or colony through Italy, which did not decree him statues, and send a deputation to pay him compliments. All Italy, to use his own words, brought him back upon its shoulders: "That one day," he says, "was worth an immortality, when, on my approach towards the city, the senate came out to receive me, followed by the whole body of the citizens, as if Rome itself had left its foundations, and marched forward to embrace its preserver." As soon as he entered the gates, he saw the steps of all the temples, porticos, and tops of houses, covered with people, who saluted him with an universal acclamation; and as he marched towards the capital, fresh multitudes expected his arrival. So splendid was his triumph, that he had reason, he says, to fear lest the people should imagine that he had himself contrived his late flight, for the sake of so glorious a restoration. After some difficulties, occasioned by the rancour of Clodius, his property was restored to him, and his demolished mansion rebuilt at the public expense. His reimbursements, however, were not adequate to his losses.

The persecution he had undergone rendered him still more cautious in his political conduct, and while he studied to keep on the best terms with Pompey, Cæsar, and Crassus, he exercised his eloquence generally as a defendant to secure him personal friendships. In the 54th year of his age he was admitted into the college of Augurs. He is said to have been above the general faith of his countrymen in augury, but the situation carried dignity with it. The death of the atrocious Clodius, who was killed in an affray, by Milo, soon after gave occasion to one of the capital exertions of his oratorial powers; and though the appearance of Pompey's soldiers discomposed, and even paralyzed his elocution on this occasion, so that Milo was banished, the pleading exists as a model of defensive eloquence.

In his 56th year he went as proconsul to Cilicia, the jurisdiction of which belonged to the isle of Cyprus. His conduct in this commission was highly honourable to his character, particularly towards the Cappadocian king, Ariobarzanes, who had been miserably scourged by the Roman governors and generals. The debt for which that unfortunate prince paid exorbitant interest to Pompey, and owed also to Brutus, seems to have placed Cicero in a situation of distressing dilemma. It shewed the humanity of our orator, however, in a high light, that when Ariobarzanes came to offer him a present, the usual peace-offering to Roman governors, he generously refused it, but pressed him to apply it to the payment of his debt to Brutus. The poor Cappadocian prince was obliged to excuse himself, by pleading the necessity of satisfying more pressing demands, namely those of Pompey, who, for good reasons, could not be refused. Brutus solicited his assistance to recover debt in another quarter, which still more eminently displayed Cicero's sense of justice. The city of Salamais owed Brutus a debt of £20,000, and Scaptius his agent (the lovers of liberty will peruse the anecdote with pain) had, in harassing the Salaminians for payment, shut up their senate till five of them were starved to death. Brutus attempted to place this Scaptius in the favour of Cicero; but Cicero, disdaining to make the ties of friendship a bond of injustice, deposed Scaptius from his prefecture, having laid it down for a rule, to grant no man *a command* who was concerned in trade, or negociating money in the province. On similar principles he had ordained, that no debt under his government should bear an interest of more than a per cent. per month. Scaptius demanded four per cent.; but though the agent for Brutus's debt, he obliged him to accept of payment on those legal terms, and helped the unhappy Salaminians to release the bond by remitting to them the dues of his own office. "If Brutus does not approve of this, (he says in writing to Atticus on the subject,) I shall be sorry indeed that he has any occasion to be angry with me, but much more *not* to find him the man that I took him to be." In another epistle to Atticus, he adds, "How could you desire me to grant troops to Scaptius for the sake of extorting money? Could you, if you were with me, suffer me to do it? If I really had done such a thing, with what face could I ever read again, or touch those books of mine with which you are so pleased?" It has been usual to tax the memory of Cicero with a pliable and timid spirit. Yet, to behave with such integrity, must have required courage as well as generosity. He restricted his own troops from even the customary foraging tributes which were levied on the inhabitants of the provinces, allowing them only house-room, and obliging them to lodge in tents when that exaction could be spared. He refused the presents of the neighbouring princes, kept a table at his own expence instead of that of the province, was accessible to all ranks of people, gentle in his punishments, and careful of the public money. In his military operations, he checked a formidable incursion of the Parthians, and took the strong town of Pindenissum. Perhaps it was fortunate for his military reputation, that there was no necessity for a pitched battle with the Parthians. His successes, however, though not splendid, were sufficient for the protection of the province, and were as complete as the occasion seems to have required. It was then customary, even on very moderate triumphs, for the army to hail their general imperator, and Cicero renewed this honour. In his applying to the senate for a supplication, and entertaining hopes of a triumph, the admirer of his virtue must regret to find an instance of his vanity. Cato opposed the decree with many expressions of regard for the truly valuable parts of his character, but deemed such honours too cheaply given. The offence which Cicero expresses on this occasion was unworthy of himself, and forms a displeasing contrast, both to the noble conduct which has been already described, and to the candid and manly sentiments of Cato on that occasion.

His approach to Rome was honoured by a vast concourse of the citizens who came out to salute him, but he found the city full charged with the dissension between Cæsar and Pompey, which was soon to explode. Cicero made use of all his influence to prevent the fatal rupture, but Cæsar was in jest when he pretended to negotiate, and Pompey was more afraid of peace than war, probably from knowing the mind of his rival. Cicero chose his side when it was no longer possible to be neutral, but with his eyes full open to the dilemma of calamities which awaited his country in the event of either rival succeeding. He seems to have dreaded the cruelty of Cæsar, more than the event justified; but his fears of Pompey's incapacity were but too well founded, and even should he have succeeded, the language which Pompey himself held, foreboded neither clemency to the vanquished nor liberty to the republic. Cæsar, conscious he could not expect Cicero's support, wished to exhort him to neutrality, and to retire into Greece. His arrival at Pompey's camp, though pleasing to the majority, excited only a momentary enthusiasm, but proved unimportant to the cause, or to his own personal satisfaction. He has been blamed for passing railleries on the prospects and counsels of his party before the battle of Pharsalia; but when he saw the real inequality of Pompey's ostentatious Asiatic parade of war opposed to the veterans of Cæsar; when he remonstrated against risking a battle, and ridiculed the overweaning confidence of his party; it is no wonder that he enforced his arguments with ridicule, and the pity was for his associates, that they did not feel the force of his rebukes. A seasonable illness excused his presence at the fatal battle of Pharsalia, and he afterwards refused all command in the forlorn cause, and took the first opportunity of returning to Italy. Indeed the cause soon was utterly hopeless. The sons of Pompey were men whose success was still more to be deprecated than that of Cæsar's, and Cato's prolonged resistance was but the prelude to a tragedy, which could have no finer conclusion than his own act of suicide. He therefore determined to return to Italy, and landed at Brundusium at this time. He was distressed in his private as well as public circumstances. The unnatural conduct of his brother Quintus, who, in order to make his peace with Cæsar, threw all the blame of their late hostility on Cicero, must have stung him deeply. In spite of this conduct, he was afterwards on terms of friendship with this brother, and they suffered, as will be seen, under a common proscription. He was likewise in pecuniary difficulties, owing to the advances he had made to Pompey, and the extravagance of his wife, so that Atticus's purse was, for the present, his chief support. The arrival of Cæsar at Brundusium, relieved his suspense. At their meeting, the generosity of Cæsar imposed no necessity of his saying or doing any thing beneath his dignity; for the conqueror no sooner saw him, than he alighted and ran to embrace him, and afterwards walked with him alone, conversing familiarly for several furlongs. From Brundusium he followed Cæsar to Rome, with a resolution to spend his time in study and seclusion, till the republic should be restored to some tolerable state. His books, which had before been only the amusement, were now become the support of his life. *A quibus antea delectationem modo petebamus, nunc vero etiam salutem.* Ep. Fam. 9. 2. In his present obscurity, he wrote his book of Oratorial Partitions. Another fruit of his leisure was his Dialogue on famous Orators, in which he gives a short account of all who had ever flourished either in Greece or Rome. The conference is supposed to be held between Brutus and Atticus in Cicero's garden at Rome, under the statue of Plato, whom he usually imitated in his manner of dialogues.

A domestic occurrence in the latter part of his life, as late as his 61st year, has impressed perhaps the only stain that can be fixed upon the bright purity of his private character. This was his divorce of his wife Terentia, and his immediately subsequent marriage with his rich, beautiful, and youthful ward Publelia. As he was involved in debt, the possession of Publelia's fortune, rather than of her person, may be supposed to have been his motive. In whatever light the match be regarded, the disparity of their years, the relationship of ward and guardian, and the separation from one who had so long been his partner, would make us wish that this part of his history had not existed. Yet his conduct was not without one apology, which, if it does not excuse, at least in some degree extenuates the proceeding. Terentia was an imperious, turbulent, and expensive woman. He had borne her perverseness in the vigour of health, and in the flourishing state of his fortunes; but in declining life, and when he was soured by mortifications from abroad, the want of domestic quiet was no longer tolerable. The divorced Terentia, we are told by Valerius Maximus, lived to the age of 103 years; and, according to St Jerome, married three husbands after Cicero, so that the separation seems neither to have affected her health nor spirits. The death of his daughter Tullia in childbed, soon after his second marriage, gave a deep wound to his sensibility; and the behaviour of his young wife, who rejoiced in the removal of her step-daughter as a rival in his affections, and whom he was at length obliged to repudiate, deprived him of his chief domestic comforts.

The conspiracy against Cæsar was concerted without Cicero's knowledge, yet the removal of an usurper was thought so conformable to his public principles, that Brutus, after the deed, waving his bloody dagger, called on the name of Cicero, and hailed him on the restoration of liberty. Cicero was well inclined to justify the action, but the turn given by Anthony to the minds of the people, deterred him from more than some general attempts to restore public concord, and at length induced him to retire into the country, where he resumed his literary pursuits. During this period he wrote his Treatise on the Nature of the Gods; his Discourse on Divination; his Dialogue on Old Age; and his Treatise on Friendship. He was also employed on a history of his own times, or rather of his own conduct, which it does not however appear that he ever intended for publication. The arrival of young Octavian in Italy, however, opened to him a prospect of serving the state, and recovering his own consequence. The crafty youth was able to persuade the aged orator that his intention was to establish the republican constitution, and become the faithful servant of the senate. Cicero, who never loved nor trusted Anthony, as soon as he thought himself sufficiently protected, by the quarrel between him and Octavian, promoted the most hostile measures against the former, and the most honourable decrees in favour of the latter; and he pronounced those famous Philippics, which, while they proved him fully possessed of all the powers of eloquence, procured him a most implacable foe. The subsequent reconciliation of the two rivals, the formation of the second triumvirate, and the triumph of their party in Italy, drove Cicero again to his retreat. The last thing which the triumvirate adjusted was a list of the proscription of their enemies. Cicero was at his Tusculan Villa with his brother and nephew when he first received the news of the proscription, and of their being included in it. It had been the design of the triumvirate to keep it a secret, if possible, till the moment of execution; but some of Cicero's friends found means to give him early notice, upon which he set forward presently with his brother and nephew towards Astura, the nearest villa which he had upon the sea-side, intending to transport themselves directly out of the reach of their enemies. But Quintus, being wholly unprepared for so sudden a voyage, resolved to turn back with his son to Rome, in confidence of lying concealed there till they could provide money and necessaries for their support abroad. Cicero, in the meanwhile, found a vessel ready for him at Astura, in which he embarked; but the weather being stormy and adverse, he only sailed about two leagues along the coast, and landing at Circaeum, spent a night near that place in great anxiety and irresolution, uncertain whether to fly to Brutus, Cassius, or to one of the sons of Pompey, and even meditating suicide. The importunity of his servants at last prevailed with him to sail forward to Cajeta, where he went again on shore to repose himself in his Formian Villa, about a mile from the coast; weary of his life, and declaring that he would die in that country which he had so often saved. Here he slept soundly for several hours, till his servants forced him into his litter or portable chair, and carried him towards the ship through the private ways and walks of his woods, having just heard that soldiers were come into the country in quest of him, and not far from the Villa. As soon as they were gone, the soldiers arrived at the house, and perceiving him to be fled, pursued immediately towards the sea, and overtook him in the wood. Their leader was one Popilius Lænas, a tribune of the army, whom Cicero had formerly defended and saved in a capital cause. As soon as the soldiers appeared, the servants drew their weapons and prepared to defend their master to the last; but Cicero commanded them to set him down and to make no resistance; then, looking on his pursuers, with a calm firmness, stretched forth his head out of the litter, and bade them do their work. They cut off his head and both hands; and Popilius, charged with the horrid burthen of that head which had preserved his own, set out with it to Rome, as the most agreeable present which he could bear to Anthony. Anthony caused the head to be fixed upon the rostra between the two hands, a spectacle which drew tears from all virtuous citizens. The death of Cicero was indeed regarded as the death-blow of the republic. Anthony regarded it as such, and declared the proscription at an end. He was killed at the age of sixty-three years, eleven months, and three days.

Cicero's literary character has come down to posterity in the double light of an orator and a philosopher. As an orator, he has no rival in antiquity but Demosthenes. In comparing them, Quinctilian has given him the preference; while Hume, Fenelon, and, generally speaking, the majority of moderns, seem to regard the Greek master of eloquence to have come nearest to the idea of perfection. In comparing geniuses of so high a description, the preference is rather an affair of taste than demonstration; and perhaps it is of more importance to appreciate the distinctive characters and particular merits of each, than to attempt that decision of pre-eminence which will always be a problem. To the clear, close, and rapid simplicity of the Greek orator, we may contrast the copious, inexhaustible variety, the deliciousness and magnificence of Cicero's eloquence. The logic of Demosthenes is irresistible, the fire of his enthusiasm is the light of conviction, his progress to the point of attack is more vehement and direct. Cicero's manner has more preparation; he studies every possible resource. The tactics of the Greek orator have been compared to an assault upon a city by storm, and Cicero to a besieger making his approaches in due form, constructing his parallels, cutting off the issues of his enemy, and surrounding him at all points. Much has been written to prove that these characteristics of their respective eloquence, arose necessarily out of the circumstances of the times in which they lived, and the people whom they addressed. That the lively and shrewd Athenians, would not have listened to the luxuriant ornaments of Cicero's style; and that the Romans were too proud to have suffered the bold and blunt appeals of Demosthenes, too grave to have required the electrifying shocks by which the Greek orator found it necessary to fix their volatile attention. Those speculative theories, however, are by no means satisfactory. The Roman senate were, at least, as shrewd judges of style, as likely to be fond of unadorned and nervous simplicity, as the mob of Athens; and if the Roman character, in general, was more phlegmatic, it was more likely, than the Greeks, to have required the electric vehemence of Demosthenes. The difference of the orators lay in their genius, perhaps, more than their circumstances. Whatever Cicero might have been at Athens, it is difficult to conceive, that Demosthenes in the forum, or before the conscript fathers, would have been equally effective as when he fulmined over Greece. It seems indeed to be generally conceded, that, for pleading to carry conviction, Demosthenes is supreme. Could we suppose them both alive at this moment, and both equally ardent and instructed in some mighty public cause which required to be supported by eloquence, could we suppose *all* the enlightened spirits who have ever perused and felt the force of their works, to be named as judges in selecting the one or other to plead that cause, *most probably* the greater number of suffrages would be that the office of pleader should be assigned to the Greek. This, if admitted, might appear at once to decide the point of superiority on the side of Demosthenes. But Demosthenes and Cicero, it should be remembered, are now submitted to posterity, not merely as pleaders, but as fine writers; and another question arises, from which of the two will the mind of their readers derive the greatest degree of pleasure? In this view of their merits, the greater variety of Cicero's subjects, the richer luxuries of his diction and imagery, the intermixture of a finer, more pathetic, and philosophical spirit in his orations, give them a value independent of the pleading which they contain, or the models of argumentation which they exhibit. Had they been opposed to the terser eloquence of Demosthenes, before an audience assembled to decide rigidly on a point in dispute, those graces *might* possibly have furnished an inferior pleading; but to posterity they afford a richer treasure of literature, and perhaps altogether a nobler exhibition of the genius of one man. The manner of Cicero, we are told, fell into discredit in the succeeding age. Some considerable authors, with Sallust at their head, struck into a closer and more sententious style of writing, pretending to emulate the purity of Demosthenes and Thucydides, though they were far from reaching it. Even in his own time, we find him replying to those censurers who reproached him for want of Attic simplicity. Brutus was of the number; although, it is clear, from Cicero's appeal against their criticisms, that what they meant by simplicity, was only a naked and starved diction, devoid of all legitimate eloquence. Under the age of Augustus, political causes contributed to debauch the Roman taste; and under that reign, it became fashionable to decry the taste and manner of Cicero. Virgil, in giving the province of eloquence to the Greeks, did not chuse to offend his patron by a compliment to Tully. The two Asinii Polliones, father and son, distinguished orators of the same age, attacked his abilities even with acrimony, and the younger wrote a book to prove that his father excelled Cicero. Augustus was himself a dabbler both in prose and verse, and probably contributed to bring a corrupted style into fashion. Mecænas was an Anticiceronian both in theory and practice. The character of authorship, which some of the succeeding Roman emperors affected, and the danger of either departing from their manner of writing, or of expressing their thoughts in plain language, together with the swarms of Greek rhetoricians who took pains to deride the eloquence of Cicero, gradually debased the taste of the world, till Quinctilian arose and reformed it, at least in as far as the reputation of Cicero was concerned, whose character as an orator he restored to its true light, concluding with these words, *Hunc ergo spectemus, hoc propositum nobis sit exemplum. Ille se profecisse sciat cui Cicero placebit.*

The philosophical works of Cicero were composed in the stormy period which drove him to retirement, between the breaking out of the war of Cæsar and Pompey, and his own death. One half of them has perished by the ravages of time. They formed a complete course of the philosophy of the Greeks, which had followers and admirers at Rome since the time of Lælius, but few expounders. Cicero was the first who had intelligence and enterprize sufficient to exhibit it in all its systems to his countrymen. Its subjects were so new to the Romans, that their language had not terms for the abstract ideas of the Greeks; and it was he who first created that metaphysical language, of which a portion disentangled from the jargon of the schools still exists in modern philosophy. He commenced with his book entitled *Hortensius*, which has been lost. Next followed his *Academic Questions*, in which he followed the doctrines of Plato. The object of his five dissertations, called the *Tusculan Questions*, is to discover the most essential means of happiness, which he reduces to five. The contempt of death; patience in affliction; firmness in different trials of life; habitual controul over the passions; and the persuasion that virtue ought to seek for no recompense but from itself. This philosophy is confessedly borrowed from the Academy, and the Portico; but it is highly embellished by his eloquence. The most pleasing parts of his work, are where he enters on the natural proofs of the immortality of the soul, and the future rewards of a virtuous life.

In his Treatise on the Nature of the Gods, his object seems to be to prove and justify a superintending providence. To find a man unenlightened by revelation, devoting the ripeness of his mind to such exalted subjects, may well surprise us; and our admiration must be complete, when we find, that, while he stands the advocate of religion, he is so little tainted with superstition. In his book on Divination, he makes every species of ancient imposture and superstition pass in review. His *Scipio's Dream*, is a fancy piece, built on the Platonic doctrine concerning the soul of the world, and the state of human souls after death. His work *De Finibus*, on moral ends, contains an account of the opinions of the several Grecian sects upon this subject, and discusses their leading arguments. His work *De Officiis*, may be properly termed the Heathen whole Duty of Man; a piece, which even Christians cannot read without advantage. His dialogues, entitled *Cato and Lælius*, the first treating on old age, the second on friendship, are extremely elegant and agreeable pieces of moral writing. His Epistles, perhaps, more justly merit the appellation, than any of the same importance, as documents of history, and models of composition, which have ever appeared. His work *De Legibus*, which explains the grounds of jurisprudence, is incomplete. His treatises *De Republicâ*, and his *Œconomics*, have unfortunately been lost.

To the list of his writings, should be added his rhetorical treatises *De Oratore;* his book *De Claris Oratoribus;* and his *Orator*, addressed to Brutus. See *Plutarch*. Middleton's *Life of Cicero*. *Ciceronis* Opera. (n)

CILICIA, was an ancient dynasty of Asia Minor, extending from the 36th to the 40th degree of north latitude; bounded on the east by mount Amanus, which divided it from Syria; on the south by the Mediterranean sea; on the west by a chain of mountains, which separated it from Pamphylia and Pisidia; and on the north by Isauria, Cappadocia, and Arminia Minor.

If we be allowed to prefer any one of the discordant accounts, found in ancient history, respecting the aborigines of this country, we would say, that it was peopled by Tarshish the son of Javan, from whom it was, at first, denominated Tarsis, and its metropolis Tarsus. The descendants of this patriarch are said to have kept possession of this region till after the Trojan war, when Cilix, a brother of Cadmus, and a native of Phœnicia, migrated with a daring colony of his countrymen, into Cyprus; and, in the restless ardour of adventure, leaving that island, invaded Tarsis, and deprived the inhabitants of their independence, and the country of its name, which, from its conqueror, was now denominated Cilicia. Several bands, both from Greece and Syria, afterwards imitated this example, and, settling in the same country, were blended with the ancient inhabitants. The names of the kings who succeeded Cilix, and the actions which they performed, cannot arrest our attention, till the country willingly yielded to the power of Cyprus, and its sovereigns resigned their independence to the Persian court. Cilicia, however, enjoyed the shadow of royalty, till the reign of Artaxerxes Mnemon, who stript it of its tributary kings, reduced it to a province of the Persian empire, and in this state of degradation it remained, till the Persian empire was extinguished by Alexander. At the death of that monarch, Cilicia became a part of the dominions of Seleucus, under whose descendants it remained, till it was subjected to the Romans, by the arms of Pompey. It was, however, under the proconsulship of Cicero that the country was completely subdued, and was formed into two divisions; the eastern part being denominated Cilicia Campestris, and the western Cilicia Aspera. The Romans, with their accustomed policy, claimed the former, which was by far the most valuable, as a province; but allowed the latter to boast of its own kings, who were, however, dependent upon the senate. But Vespasian deprived even this division of the last appearance of independence, and divided again the whole region into Cilicia Prima, formerly distinguished by the epithet Campestris. Cilicia Secunda, comprehending the maritime part of what was before denominated Aspera, and Isauria, which included the interior of the same district. In this state it remained, till the Roman territory was divided under Honorius and Arcadius, when Cilicia naturally followed the fortunes of the eastern empire. When the eastern empire proved, at last, unable to preserve its boundaries from violation, Cilicia was torn from it by its bold invaders, and, after experiencing all the vicissitudes which have since agitated Asia Minor, it now forms a part of the extensive province of Caramania.

The whole region of Cilicia was surrounded by rocky and precipitous mountains, which defended it like a wall, and left it accessible only by three narrow passes, emphatically called the gates of Cilicia, one leading from Syria, a second by mount Amanus, and a third by mount Taurus. The eastern division, formerly denominated Cilicia Campestris, was, as the name imports, a level and a beautiful country, abounding in fruits and grain. The western division, called Cilicia Aspera, or Trachæa, was rough, stony, and mountainous, but compensated for its sterility, by producing excellent horses, which are still in great repute. The air, in the interior, is favourable to health and longevity; but on the sea-coast diseases, of a dangerous nature, frequently prevail. The principal rivers which fertilize Cilicia, as they roll to the Mediterranean, are the Selinus, the Calycadmus, the Lamus, the Cydnus, the Serus, the Pyramus, and the Pinarus. The metropolis of this dynasty was Tarsus, now Tarasso, situated upon the Cydnus, and celebrated, in ancient times, as the rival of Athens and Alexandria, in every department of art and of science; and still venerable as the birth place of St Paul, who, when fame shall be conferred in proportion to the blessings of knowledge, of civilization, and of happiness, which the world has received from its benefactors, shall be accounted the first of human characters. It would be inconsistent with our plan to enumerate all the cities of this region, which are mentioned in ancient history: we may add, however, that Soli, built upon the sea-coast by the Greeks and Rhodians, who, mixing together, lost the purity of their native languages, is said to have given occasion to the term *solecism*, which is still applied to an impropriety of expression. Anazarbum, situated on the Pyramus, was the native city of Dioscorides: Issus, now Aisse, on the borders of Syria, was famous for the battle of that name, fought between Alexander and Darius, and for the defeat of Niger by Severus: And Sarpedon is well known by the famous temple which it contained, consecrated to Apollo and Diana. CINALOA, or SINALOA, a province on the western coast of New Spain, in the intendancy of Sonora; extends from the Rio del Rosario, to the Rio del Fuerté. It contains five towns, 92 villages, 30 parishes, 14 farms, and 450 cottages. In 1793, the number of tributary Indians amounted to 1851. The following are the principal towns of the province, viz.

Culiacan, formerly Hueicolhuacan. Population, 10,800.

Cinaloa, or the Villa de San Felipe y Santiago. Population 9500. W. Long. 107° 56′. and N. Lat. 25° 57′.

St Rosario, situated near the rich mines of Copala. Population 5600.

Villa del Fuerte, or Montesclaros. Population 7900.

Los Alamos, which is the residence of a *disputacion de Mineria*. Population 7900.

The statistical account of this province will be given, with more propriety, under the article SONORA. (W)

CINCHONA, or, as it is commonly called, *Peruvian Bark*, is obtained from several species of the genus Cinchona, which belongs to the class Pentandria, order Monogynia, and to the natural order *Contortæ*. Twenty-five species have been described by the Spanish botanists as natives both of North and South America. Our observations, from the imperfect nature of the information which we possess, must be confined to the genus, and must not extend to the species. The cinchona is a tree which is found only in mountainous tracts, where it grows to the thickness of a man's body. The Spaniards have never yet attempted to cultivate it, but merely strip the natural trees of their bark; a practice which must ultimately destroy the genus, as they always die after being deprived of their bark. This operation is performed in the dry season, which is from September till November. The bark being well dried in the sun, is packed up in skins, so as to form bundles of one hundred, or one hundred and fifty pounds weight. These packages are called Lerdone by the Spaniards: they contain all the species, which are afterwards sorted according to their quality.

Three kinds of bark are in use as a medicine in Europe. Of each of these we shall give a brief account, and afterwards conclude with a statement of the modes of preparation most commonly employed. The following are the varieties enumerated by the Edinburgh College.

1. Common bark.
2. Yellow bark.
3. Red bark.

1. *Common bark.* Several varieties of this species of bark are brought to Europe; the quilled variety from Loxa, and the flat from Guanaxo, are the most remarkable. The former of these comes over in pieces four or five inches long, rolled up very thin, externally of a grey-

ish brown, internally (when fresh broken) of a bright cinnamon colour. Its fracture is clean and even. Its taste is bitter and astringent, its smell peculiar but aromatic. The latter variety is imported in flat, coarse, and thick pieces; and still farther differs from the quilled bark in having a much darker colour externally. In every other character it corresponds with the former. Both are said to be equally efficacious.

2. *Yellow bark.* This is less rolled than the quilled bark; its pieces are also larger and thicker. It has a much deeper red colour. Its fracture is fibrous, and in powder it is much paler than in its entire state. Its taste is more powerful, though the smell is weaker, than the common bark. Its active principles are more abundant. This bark has been only introduced into use since the year 1790, by Mutis, who considers it to be the only variety which possesses a real febrifuge quality.

3. *Red bark.* This variety is sometimes rolled, but more commonly is in flat, thick, large pieces. It is heavy, firm, and dry. It has a smooth fracture. It is composed of three layers. When powdered, it has a reddish colour. It is more bitter and astringent than the common and yellow bark.

All the varieties of cinchona are highly valuable, and are consequently liable to be adulterated with various substances. It is therefore necessary to attend, in selecting this drug, accurately to all of its characters.

Cinchona has been long known as a medicine in Peru, where the natives are said to have adopted its use, from observing animals recur to it. Whatever may have been the source of its first employment, it was not tried by Europeans until the year 1640, when the Countess of Cinchon, the wife of the Spanish viceroy, was cured of the ague by means of it. It therefore derived its present name from her. It has also been called Jesuits bark, from the exertions made by these disciples of Loyola to introduce it. As it usually happens on the first appearance of any novel remedy, considerable opposition was made to it by several eminent physicians; but its efficacy soon overcame the groundless clamour which had been excited.

Probably no vegetable substance has undergone so many analyses, by the most distinguished chemists of Europe, as the different kinds of cinchona have been subjected to, and yet little positive knowledge has been obtained of its constituent parts. The following are the most important results that have been obtained respecting the composition of the different varieties of cinchona: To enter into a minute detail of the analyses of the individuals would far exceed our limits. The bases of all the varieties is *ligneous fibre*, combined with which there are several other principles which may be extracted by means of proper solvents. In all the varieties, they correspond, except in the proportion and consequent activity. A cold infusion of common bark has a bitter taste and slight peculiar odour; when a common heat has been employed, a larger quantity of the active principles is dissolved, but the complete solution ceases, on cooling, as is indicated by the turbidity of the fluid. A decoction of this bark has a very astringent taste, and a deep brown colour. On cooling, its transparency is destroyed, and a precipitate is deposited, that is soluble in alcohol. Much heat destroys all the active principles of the bark by decomposition. Alcohol, in all its modifications, is a powerful solvent of the active principles of cinchona. A solution of ammonia is also a powerful solvent of them. Vinegar acts very imperfectly on them.

The agency of the different menstrua on the red and yellow varieties of the cinchona, produces apparently the same results as on the common or pale bark, varying, however, very considerably in degree; the red being more powerful than the common, and the yellow still more so than the red.

It is an object of considerable importance, as well as of curiosity, to determine exactly the proportions in which the different principles exist, in the varieties of bark, as well as the relations which these principles have to their efficacy as a medicine; but, unfortunately, the difficulties which are opposed to the analyses of such fleeting and delicate substances, as the principles of vegetables, render this desire unavailing, at least in the present state of science. The greater solidity of the principles of bark in hot water and in alcohol, would induce a belief of its being a resin; while, on the other hand, their partial solidity in cold water, and their decomposition even by a moderate degree of heat, are characteristic of the extractive principle.

The effects of chalybeates on the infusions of Peruvian bark, indicate the presence of an astringent matter, which seems to be intimately connected with the substance extracted by heated water or by alcohol. The addition of a solution of the sulphate of iron to the infusion, strikes a dark olive green colour; a deeper shade of the same colour is produced by this salt in the decoction or tincture. From this fact, it has been inferred, that tannin is present, and, consequently, that a precipitate would be produced by a solution of gelatine. This effect, however, is only induced in some varieties of the Peruvian bark; there being others, the infusions of which are not, in the slightest degree, affected by the addition of gelatine, but yield a precipitate on the addition of tannin. These singular phenomena have given rise to a very absurd hypothesis of Seguin, in which he ascribes the agency of Peruvian bark to the presence of gelatine.

Dr Duncan ascribes these effects to a new agent, which he calls cinchonin. Vauquelin has made extended experiments on the different species of cinchona, but they are of less value than they would have been, had he detailed the specific characters of each. Mr Murray has found, “that the watery infusion of the pale bark is not sensibly precipitated either in gelatine or tannin; that of the red bark is not precipitated by gelatine, but gives a copious precipitate with tannin; and that of the yellow is rendered turbid by gelatine, and precipitated copiously by tannin.” It is vain to throw out conjectures, as to the nature of this substance, until farther facts be determined, on which we can rest with greater certainty.

Vauquelin has determined the presence of a peculiar acid, to which he gives the name of *kinic* acid, in some varieties of the bark.

The active principles of bark are rendered more soluble in water by the acids, the alkalies, and some of the earths, more especially magnesia.

Much diversity of opinion prevails among medical men respecting the relative efficacy of the three kinds of bark which we have enumerated. The red bark, when first introduced into English practice, in consequence of a Spanish vessel, freighted in part with it, being taken in the year 1779, was tried in several of the London hospitals, and was then, as is usual with every new remedy, extolled to the skies; but its reputation has given way to that of the yellow bark, which is *now* generally considered to be most efficacious.

The preparations of bark, which are admitted into the British Pharmacopœias, are, the decoction, the extract, the infusion, the tincture, and the compound tincture. The powder is unquestionably the most efficacious when the patient's stomach can bear it; and the other preparations must be resorted to when its use is inexpedient. Of these, the extract appears to be the least calculated to do any good. The practitioner must be guided, in a great measure, by the habits and delicacy of the patient. See MEDICINE.

It is utterly impossible to say in what manner the Peruvian bark acts on the human constitution. In general, it is considered tonic, antiseptic, and astringent, and it may possess all of these qualities in a very pre-eminent degree; but still no clue is furnished by them to develope the mode in which it acts in the cure of disease. Thus, for example, every physician is well acquainted with the symptoms of intermittent fever, but there are few sufficiently daring to arrogate any decided knowledge of the causes of these symptoms; every practitioner has some hypothesis of his own, but if he be a man of common sense, he will never make that the basis of his practice. In like manner, experience has shewn, that Peruvian bark almost universally cures this fever; but how this cure is induced, it is impossible to determine, until we are assured of the nature of the diseased action which it overcomes. The effects of bark are very powerful; and it is a very remarkable fact, that its action is imperceptible on the human constitution. The only effects of an overdose, are headache and nausea. Whatever difference of opinion may prevail respecting the mode in which the Peruvian bark produces its effects, there is no doubt of the very decided character of these effects. In intermittent fever it was first used, and what is very rare in the history of medicine, still maintains its pre-eminence over every other remedy in general application. Experience too has taught almost the whole host of medical men, that it may be administered very safely in large quantities, in all stages of the disease, without any other preparation than that of previously evacuating the stomach by an emetic, or by a cathartic. It has been supposed most useful when exhibited before the recurrence of the paroxysm. It may be given even in the hot stage, though it is then more liable to induce nausea. But the more common mode of practice is to administer it during the interval of the paroxysm. Frequently very smart attacks of intermittent fever have been cut short by the timeous use of this medicine. The usual dose is from one to two scruples every fifth or sixth hour during the intervals of the paroxysms, and this should be continued for some time (which must be determined by circumstances) to prevent a relapse.

In remittent fever, particularly the bilious remittent of hot climates, even where the remission is very obscure, bark may be administered with great freedom, and very generally with much advantage.

It is given in diseases of debility, such as typhus, cynanchi maligna, in passive hæmorrhagies, confluent small-pox, in dysentery. It is also employed in scrofula, ill-conditioned ulcers, &c. In the first of these classes it does not appear so beneficial as wine, from the weak state of the organs of digestion. When the patient is convalescent, it is considered more useful.

Bark has been used very freely in rheumatism, particularly among the London practitioners, and very generally with advantage. It is the object of another article to enter more fully into the uses of this very valuable remedy.

Half a drachm is the usual dose; but, under particular circumstances, the quantity may be very much augmented. Two ounces have been taken, in urgent cases, in the course of twenty-four hours.

The powder, as before hinted, is the most efficacious form in which it may be administered, either mixed up with water, milk, jelly, or any other simple vehicle, or combined with some stimulant aromatic matters. It sometimes excites vomiting and purging, which must be corrected by the usual means. See Thomson's *Chemistry.* Murray's *Materia Medica. Pharmacop. Collegior. Lond. Edin.* &c. *Practice of Physic,* (passim) *Thomas* and *Cullen.* See also MEDICINE. (C. M.)

CINNAMON. This well known spice is the bark of the *Laurus cinnamomum*, which is cultivated both in the spice islands and at Cayenne, though most abundantly in the former, whence almost the whole of the cinnamon for the European market is brought. The characters of the *laurus cinnamomum* are given under the article BOTANY. It belongs to the class Enneandria, order Monogynia, and to the natural order Oleraceæ.

Captain Perceval has given the fullest account of this plant that has ever met our eye, and the following account is substantially derived from his History of Ceylon. The cinnamon gardens are within half a mile of the fort of Columbo in Ceylon. They extend over a surface of more than 15 miles, which is traversed by various roads. There are also plantations of the shrub at Madeira, and Point de Galle. It thrives best in a loose white sand. It has a slender trunk, rises to the height of from four to ten feet, innumerable branches shoot from the stem, and give it the appearance of the Portugal laurel. The wood is light and porous like that of the osier. It is used as fuel. Shoots spring up from the roots in immense profusion. The leaves, when they first burst, have a beautiful scarlet colour; they then become green, and have both the taste and the smell of cloves. The blossom is white, and has no smell. The fruit resembles an acorn. It is ripe at the end of autumn, when oil is obtained by bruising and boiling it. The natives anoint themselves with the oil, which is skimmed off, and they also mix it with cocoa nut oil, and burn it in lamps. During all audiences with the sovereign of Candy this oil is burnt. When the trees become too old, they are cut down, and their places are soon occupied by young shoots, that rise from the roots in vast profusion. Formerly, many of these young twigs were cut as sticks, which are highly prized; but this is now prohibited.

The natives divide the true cinnamon into four classes. 1. *Rasse curundu*, or honey cinnamon, which is known by its broad thick leaves. 2. *Na icurundu*, or snake cinnamon, which is also known by the size of its leaves. 3. *Capuru curundu*, or camphor cinnamon, which is very inferior to the former too. The root yields camphor by distillation. 4. *Cabatte curundu*, which is harsh and astringent. Its leaves are also smaller. There are other species of cinnamon, which are entirely rejected by the servants of government.

Originally the cinnamon tree was wild, but one of the Dutch governors raised it artificially. The cultivation was neglected by his successors, until the capture of Ceylon by the British. The plantations are now in regular rows, which facilitates the gathering of the spice.

The bark may be collected at any period of the year; but there are two seasons at which the regular harvests are gathered in. The first of these takes place between the months of April and August, and is called the great harvest; the second lasts only one month, from the end of November to the beginning of January. The whole barking is carried on by a particular class of the natives, called Schjalias by the Dutch, and Choliahs by the English. These are again divided into different ranks, and are all subordinate to a man, that receives the title of Capitain Canaillé. Every district furnishes a quantity of cinnamon proportionate to its extent, and the number of its inhabitants.

The branches which are three years old are lopped off; the epidermis is scraped off with a knife, having one side concave, and the other convex: the true bark is then ripped up, loosened by the convex side of the knife, and separated from the wood. The smaller portions are then put into the larger. They are then dried in the sun. When the drying is complete, the cinnamon is packed into bundles, which weigh about 30 pounds. These bundles are bound with bamboo twigs. They are then marked and numbered. These different processes are performed by different classes of the choliahs.

When the cinnamon is brought to Columbo, previous to its shipment for Europe, it is examined by the surgeons in the Company's service in rotation; and this is a most painful duty, as the only test is the taste. The continued chewing of this pungent substance, excoriates the mouth in spite of the utmost precaution. Experience has shewn, that the evil effects of the chewing is best alleviated, by occasionally eating bread and butter.

The best cinnamon should not be thicker than thick writing paper. It should be rather pliable, of a yellowish colour. It should have a sweet taste, and not be so pungent as to produce pain. The inferior kinds are thicker, darker, more pungent, and bitter. After the examination at Columbo has been finished, and the different kinds of cinnamon separated, they are packed into bundles four feet long, and weighing eighty-five pounds, five of which are allowed for waste in the passage. The bundles are wrapped up in coarse cloth made of hemp, or of the fibrous part of the cocoa nut tree, and the interstices are filled up with black pepper. This latter practice is said to improve the flavour of both spices.

The refuse is put into tubs in quantities not exceeding one hundred weight, and being covered with water, they are allowed to macerate for six or seven days. A small portion of the incumbent liquor is distilled from a copper alembic into glass vessels. One tub requires twenty-four hours for distillation. The fluid which passes over has a milky appearance, the oil floats on the surface, from which it is skimmed off, bottled, sealed, and locked up. The finest has a bright gold yellow colour, and the flavour of cinnamon in a very high degree.

From the distillation not having been carried on since the British have been masters of the colony of Ceylon, the price is risen from three-fourths of a Dutch ducat to 10*l.* or more per pint.

The Dutch were accused of deteriorating their cinnamon, by substituting the distilled bark, and cassia bark; but this fraud is easily distinguishable.

Captain Perceval considers the cultivation of this valuable spice to be susceptible of much improvement.

Cinnamon is one of the most agreeable of the spices. It is valuable in household œconomy, and the oil is also useful to the medical practitioner. It is stimulant, and may be employed in cramp of the stomach, &c.; but it is chiefly employed to conceal disagreeable odours and taste in other drugs. See Perceval's *Account of Ceylon* (C. M.)

CINTRA. See BRITAIN, p. 696, and ESTREMADURA.

CIPOLI. See NEPAUL.

CIRCÆA, a genus of plants of the class *Diandria*, and order Monogynia. See BOTANY, p. 93.

CIRCARS. See INDIA.

CIRCASSIA, a country of Asia, situated between 40 and 50 degrees E. Long. and between 45 and 50 degrees N. Lat. It is bounded on the north by the river Don; on the east by the Caspian Sea, and the mouths of the Volga; on the south by Mount Caucasus, and the Black Sea; and on the west by part of the Black Sea, and the Lake of Azof. The face of the country is pleasantly diversified with mountains, valleys, woods, lakes, and rivers, and in respect at least to its natural state, the soil is far from being devoid, in a reasonable degree, of the elements of fertility. The defects that in this particular present themselves, appear to be the consequence chiefly of a want of proper culture.

General aspect.

Manners of the inhabitants.

Circassia is inhabited by a warlike race of people, who having expelled or subjected to their dominion the greater part of those tribes, which at earlier periods had obtained possessions in it, spread themselves by degrees over the whole region. They now constitute one of the most considerable of the seven nations inhabiting the Caucasian mountains, and the territory in their environs. Among this people, there seems to be established a complete system of feudalism, not unlike that formerly exercised, though with still greater severity and cruelty, by the German knights, in Prussia and Livonia. The princes and nobility here, accordingly, may be considered alone to constitute the nation, who, both in their intercourse with one another, adhere rigidly to the principles of a feudal subordination, and are guided by the same views in the treatment of their subjects. The latter almost uniformly are captives, subjugated in war, but from adopting the language, and accommodating themselves to the wishes of their conquerors, they are usually treated with lenity. The chiefs and knights among the Circassians pursue ordinarily no other business or recreation, than war, pillage, and the amusements of the chase. They live a lordly life, wander about, frequent carousals, and concert and undertake freebooting, or military excursions. The knights keep the lower classes of the people in a due state of order and submission, but are themselves no otherwise subject to the chiefs or princes, than by the obligation of yielding their personal service in war. Vassals, or boors, are considered as hereditary property, and are bound to yield an implicit obedience to their masters, holding, indeed, at their disposal, not barely their possessions, whatever these may be, but even their persons, and their lives. Few instances, however, occur of their being actually sold into bondage; for generally, though not restrained by any positive laws, the prince considers it his interest to secure the affection of his subjects, and entitle himself to their fidelity in war, by a liberal and benevolent conduct. The peasantry, consisting of vassals naturalized, and slaves more recently taken in war, who fall afterwards into the same class, plough the land with large ploughs drawn by six or eight oxen; they attend to the pasturage of their flocks, carry the necessary timber and fuel from the forest, build the houses, get in the harvest, and make hay, which during winter is commonly consumed on the spot. In the time of harvest, they are assisted in their labour by the women and grown up girls. When in the course of such occupations, these people have occasion to remove to some distance from the villages, they immediately construct huts, by joining poles, which they cover with branches of trees and long grass, so that they almost resemble hay-stacks. It is in huts of a construction somewhat similar to these that the princes encamp, when in the course of their constant expeditions, and equestrian rambles, they are obliged at any time to remain for a season stationary.

It is an established usage here, that each male of the peasantry is obliged to work three days at hay-making either for the prince or nobleman, to cut wood in the forest for three days, to carry both the hay and wood to their habitations, and for every bullock that he possesses to deliver a cart load or seven sacks of millet. A bridegroom of this class is under the necessity also of giving to the lord of the manor two cows and two oxen, in return for obtaining his consent to marry. The inhabitants of the mountains, consisting of several subordinate tribes, which the Circassian princes have succeeded in subjecting more or less to their authority, give, in general, for each family, only one sheep, or its value in felts, felt-cloaks, cloths, copper vessels, or other articles like these, of primary and indispensible use. Every boor who possesses sheep, whether his flock be large or small, is required during the encampment in summer, to contribute one sheep to the prince's household, who is thus enabled to maintain continual hospitality. It will be understood, that the Circassians, like the other Tartars in their vicinity, are accustomed to quit their towns in summer, and to encamp in the fields, occasionally shifting their stations, along with their flocks and herds. In these excursions, the women and children are carried in waggons, which are a kind of travelling houses, and drawn by oxen or camels; horses, notwithstanding the excellent breeds of these animals in this country, are never used here for draught.

Villages. The Circassians usually dwell in villages, which, partly on account of the increasing filth, partly from the insufficient security which they afford, or other causes, they from time to time desert. On such occasions, the dwelling places are demolished, the timber together with the household furniture is carried off, and what cannot be removed is burnt. The attention of the migrating horde is next directed to the choice of a convenient situation, on which to erect a new village. If the spot chosen for this purpose is at a distance from water, they conduct with much ingenuity a canal from the next rivulet, by means of it to obtain a supply of this essential article. The houses are built contiguous to each other, in the form either of a circle or square, and so that the inner space serves as a common large cattle yard, provided with only one gate, while it is altogether inclosed, and as it were defended by the circumjacent houses. The dwelling of the Usden, which is commonly large and commodious, and fitted up in such a manner as to afford to the occupants every desirable convenience, stands apart from this group of buildings, destined for the use of the general mass of the population. Small solitary houses, or rather square rooms, with every suitable appendage, are built here and there for the accommodation of visitors. This is all that occurs in these parts, in the character of public inns, which indeed are unnecessary among a people whose hospitality is such, that they will contend with each other who shall entertain any stranger that happens to come among them. There are also erected occasionally in the open fields, round huts of wicker work, containing a pit to be used as a place of retreat. In the vicinity of the village are placed stacks of hay and corn provided with a fence, and the corn that has been thrashed is sometimes preserved in large baskets, fixed for that purpose on the ground, and secured with covers.

Houses. The houses of the Circassians are constructed in the form of oblong squares, and are commonly not more than from four to five fathoms in length, and about nine feet broad. The walls are made of close wicker-work, carefully plastered on both sides with clay; and on the posts which support the walls the flat roof is placed, consisting of light rafters covered with long grass. The female and the male parts of the family commonly occupy their separate and appropriate parts in the dwelling; and, generally, both in their houses and villages, as well as in respect to their clothes, diet, and other matters of domestic or individual economy and arrangement, much attention is paid to neatness, cleanliness, and order. **Dress.** The dress worn here by the men, is neat, light, and becoming. Above the lower part of it, which is made of a sort of light stuff, persons of distinction wear sometimes a short rich waistcoat, as it were to supply the place of armour, and this either with or without a great coat. The upper dress, consisting either of cloth or other strong woven stuff, is somewhat shorter than the under garment; the sleeves are slit open, and frequently bordered with furs. The breeches are provided with knee-straps, and the seams bound with small lace or embroidery, which the women very skilfully manufacture of gold and silver threads. The upper garment is regularly furnished with a small embroidered pocket on each side of the breast, for containing cartridges. The whiskers are suffered to grow; and on the head, which is shorn in the Polish fashion, there is worn an embroidered cap, quilted with cotton in the form of a melon, but occasionally lower, and, amongst the wealthy especially, ornamented with various gold and silver laces. It is a custom of this country, that the girls, between the 10th and 12th years of their age, are provided with laced stays, or a broad girdle made of untanned leather; which singular coat of mail, as they are obliged to wear it till their wedding-night, is among the common people tightly sewed round the waist, or in the higher classes fastened with silver hooks. The gordian knot thus formed, the bridegroom, at the time specified, undoes with a sharp-cutting dagger: a ceremony not unfrequently attended with danger. Over the shift the younger females wear a laced jacket, because the petticoat, which reaches to the ankles, is open along the whole front, and resembles that of a man; but married women dress in wide breeches. The cloaks worn by the women are longer than those, in other respects generally of a similar description, that are in use among the men. They are likewise frequently white; a colour of which those of the men never are. The head-dress worn in earlier years, consists of a simple cap, somewhat similar in form to that used by the males. This is usually of a red or rose colour, but varying as to richness and decorations with the rank of the parties. Under it the hair is turned up in a thick queue, which is covered with linen. This mode of dressing is continued till after the female has been delivered of her first child, when she begins to cover the head with a white handkerchief, drawn close over the forehead, and fastened under the chin. When females have occasion to leave the house, they wear a sort of wooden clogs, to keep their feet clean, and at the same time make use of mittens on their tender hands. Painting the face is considered as an indication of the want of chastity; but it is allowed to girls to dye the nails of their fingers with the flowers of the *balsamina*, which, in the language of the country, is known by the name of Kna.

When a prince, or Usden, pays a visit in full dress, he is arrayed in all his accoutrements and coat of arms, with sometimes also an additional jacket of mail. Those coats of mail are manufactured of polished steel rings, and imported partly from Persia, partly from Kubesha, to the nations inhabiting the Caucasian mountains. The helmet and the arm-plates, from the former of which a net of ringlets hang down as far as the shoulders, are manufactured of polished steel. In the girdle there are usually stuck a dagger and pistols; and the bow and quiver are fastened round the loins by straps. In common visits, the coat of mail is worn under the upper dress, the head is covered with an ordinary cap, and the only armour used is a sabre. Without the sabre, persons of wealth and rank never leave their houses; nor do they venture beyond the limits of the village, without being completely arrayed, and having their breast-pockets supplied with ball-cartridges. When persons of the lower classes do not carry a sabre, with other arms, they provide themselves with a strong staff, two arshines long, on the top of which is fixed a large iron head, and on the lower end a sharp iron pike, of the length of about eighteen inches. This sort of dart they are accustomed to throw with much expertness. In their dress, generally, there seems not to be a very scrupulous adaptation among the people in this rank of life, between what they wear and the state of the weather, as it is not unusual to see them walking in the fields, dressed in their shaggy felt cloaks, called Burke, even in the warm days of summer. Instead of the material mentioned, these cloaks are sometimes formed of sheep-skins. They are fastened at the neck with a string; and, not being large enough to cover the whole body, they are necessarily turned round upon it, according to the state of the wind and weather.

Appearance of the inhabitants.

The Circassians are, upon the whole, a handsome race of people. The men, especially in the higher classes, are mostly of a tall stature, thin form, but Herculean structure; they are very slender about the loins, have a small foot, and uncommon strength in the arms. Some of these particulars in their conformation are not produced, however, altogether independently of artificial aid. It is a practice here, to compress the waist as much as possible from early infancy, for the purpose of securing that uncommon thinness between the loins and the breast, which is so prevalent a characteristic of the people of this country; and the unusual smallness of their feet, is no doubt the consequence, in some degree, of their forcing them, as they are accustomed to do, in the tightest manner within their Morocco slippers. Yet nature has not been unkind to this people. The males, for the most part, possess a truly Roman and martial appearance, though not entirely unmarked with traces indicative of the existence in some of them of a mixture of Nagai blood. The women, if not uniformly Circassian beauties, are yet generally well formed, have white skins, smooth clear complexions, beautiful black eyes, with dark brown or black hair, which they dispose elegantly in tresses on the two sides of the face, and regular features. The loveliness of their countenances, which are always in full view, it not being the custom here, as in most of the other provinces in these parts to have the face covered, is rendered yet more attractive, through the effect of their good humour, and the lively freedom of their conversation; and the *tout-ensemble* of an engaging appearance is favoured by the elegance of the head-dress. Altogether, the instances are few of an equal or a greater proportion of beauty being to be found in an unpolished nation. As in the case of the males, indeed, nature is, with a view to this object, assisted as far as may be, and seconded by art. According to the Circassian idea of elegance of form, a woman ought to have a very narrow waist, and the abdomen should protrude toward the lower extremities. What is deemed, in these respects, the most advantageous conformation for a woman, the girdle of chastity, before mentioned, may have its use in realising. Its efficacy is at least conspicuous in the astonishing smallness of waist that is here so prevalent. The shoulders indeed are, by the same means, rendered proportionally broad; but this defect is little thought of, on account of the beauty of the breasts, to which this treatment is equally subservient, and which it is the fashion of this country very much to expose. In order to promote the same end, the girls are very sparingly nourished, their whole allowance consisting simply of a little milk and pastry.

Rural and domestic œconomy.

As to their rural and domestic economy, it is to be observed, that the Circassians both cultivate the ground, and devote a considerable portion of their time to the rearing of cattle. Their principal species of grain is millet, of which are made cakes, hasty puddings, various kinds of pastry, as well as the liquor called by them hautkups. Maize, or Turkey wheat, is also much cultivated, and used as a substitute for other food, especially during journeys, and on military expeditions. Several culinary vegetables, such as carrots, turnips, the turnip-rooted cabbage, onions, gourds, and water-melons, are likewise planted in gardens. The species of domestic animals attended to are chiefly goats, sheep, oxen, cows, and horses. The sheep, generally, are an excellent race, of a white colour, and long tails, and produce a fine wool. The horned cattle are of a small size, and are much employed in drawing the two-wheeled carts used in the country, known by the name of Arbes. The care of horses, as might be expected to be the case among roaming and predatory knights, is in these parts a very particular object of attention. In conducting this business, which is prosecuted with a zeal and assiduity suited to its conceived importance, the Circassians aim not merely at beauty, but also at strength, ability to endure hunger and fatigue, and at superior swiftness; all qualities necessary to secure the success of the expeditions of one kind or another in which they are so frequently engaged. They pride themselves much on the supposed excellence of their horses; and almost every princely and noble family boasts of a particular breed, which is marked out and distinguished by the impression upon the animals when young, of the characteristic mark of the race. In this matter, so scrupulous is the adherence to custom, so conscientious the regard to the strictest rectitude, that any one who should attempt to burn a character expressing noble descent on a foal of common extraction, would, for such a forgery, forfeit his life. The Circassians rear, moreover, poultry of almost every species, such as chickens, geese, ducks, and especially Indian fowls of a peculiar size and beauty. They pay considerable attention to the cultivation of bees, on account of the intoxicating quality of the mead, which is their favourite beverage. These bees they keep in hives placed on stocks, and carry them along with them as they remove and change their habitations.

The manufactures or commerce of the Circassians seem to be but inconsiderable. The points of their arrows are the only articles of iron which are wrought up by themselves. Their women make a very strong thread of wild hemp, but are not acquainted with the art of weaving linen. Of the wool produced in the country, part is carried to market in a raw state. Of the finer portions of the remainder, the women prepare very good cloths, but which are narrow, and remain undyed. Of such cloth, there are manufactured entire upper dresses for sale. The black and coarse species of wool is used for felt cloaks, which are of a texture singularly light and durable. A few articles of leather, embroidered housings for horses, &c. are also fabricated in this country. The principal traffic of the Circassians consists in slaves, honey, wax, skins of cattle, deer, and tigers. Their agricultural produce is barely sufficient for their own use. Sheep and horses are considerable articles of their commerce, particularly the latter, which sell at very high prices. They have no money, and their whole commerce is carried on by exchange. Upon the whole, the balance of trade would be considerable against them, but for the number of slaves which they frequently obtain in their predatory excursions. These are chiefly Georgians; and the daughters of such slaves receiving the same education, and being fashioned to the desired shape in a similar manner as the young women natives of the country, are sold, according to their beauty, from L. 20 to L. 100. These latter, it is said, enter also themselves largely into the same description of traffic, being sold for the use of the seraglios in Turkey and Persia, where they often marry to great advantage, and thus make the fortune of their families. The merchants who come from Constantinople to purchase these girls, are generally Jews, who, as well as the mothers, are reported to be extremely careful in preserving the chastity of the young women, knowing the value that is set by the Turks, particularly, upon the marks of virginity.

The two opposite customs, or laws, those of hospitality and of revenge, are in general and sacred observance with the Circassian knights, as amongst most others of the nations of the Caucasus. The former, distinguished by the name of Kunak, is established on fixed principles; and every person submitting to its protection, is, of consequence, perfectly secure from all injuries. He who receives a stranger into his house, defends him, if the occasion requires it, not only with his own blood and life, but also with that of his relatives. He furnishes him at his departure with an equestrian escort, is answerable for him to his kinsmen; and his murder, or any insult offered to him, is punished as severely as in the case of a relation. A stranger who intrusts himself to the patronage of a woman, or is able to touch with his mouth the breast of a wife, were he an enemy, or even the murderer of a kinsman, is, in consequence of the interest thus secured to himself, spared and protected as if he were a member of the family. Bloody revenge is practised with an equally conscientious and scrupulous precision. The murder of a family-relation must be avenged by the next heir, or the nearest in blood, even though he was an infant at the time when the deed was committed. For the accomplishment of this purpose, every description of vindictive malice is allowed; but either in a more public, or a more clandestine manner, the life of the murderer must be taken away, if the injured party would not subject himself to the penalty of being considered and treated as an outcast from society. Nay, this desire of revenge is hereditary in the successors and the whole tribe; and such is the spirit of resentment, that even all the relations of a murderer are considered to be involved in his guilt. It is through this extreme infatuation to avenge the blood of relatives, that most of the feuds are generated, and the occasion, consequently, produced for so much bloodshed among all the nations of the Caucasus; for unless pardon be purchased, or obtained by intermarriage between the hostile families, the principle of revenge once excited, is thus in danger of being propagated to the latest generations. There is such a thing known in these regions as the price of blood. The name by which such a compensation is distinguished, is Thlil-uasa. Princes, however, and nobles, accept of no price in such a case: it is an established law among them, to demand blood for blood.

Education.

The education of the children of the Circassian princes, is of a nature calculated to suppress from the earliest infancy every feeling and affection peculiar to consanguinity. Sons and daughters are, immediately after birth,[*] entrusted to the care of a nobleman, frequently none of the most wealthy of that order;[†] and the parents, especially the father, have no desire to see a son, till he is grown up and capable of bearing arms, nor a daughter till after her marriage. The foster father of a young prince, is obliged to take upon him the whole charge of his education; he instructs him in all the schemes of robbery which are in greatest estimation amongst those equestrian knights, and provides him with arms as soon as he is strong enough to wield them. In return for all which attentions to initiate him in the predatory arts, he receives from his grateful pupil, at his entrance into life, the greatest share of the booty which he is able to obtain. In the education of the female children, it is a primary object, at whatever expence to them of privation and wretchedness, to give them the desired slenderness and elegance of form. They are trained to all ornamental work in the domestic economy of females, especially to embroidery, weaving of fringe, sewing of dresses, and the plaiting of straw-mats and baskets. A nobleman entrusted with the education of a young princess, is required, in fine, to procure for her a husband of an equal rank, or, in default of that concluding service, he is liable to be punished with the loss of his head.[‡]

In their amusements, the youth of both sexes among the Circassians freely converse with each other,* as, indeed, in more advanced life, the women of this country are generally neither confined nor reserved. In every thing, however, relative to marriage connections, the most particular attention is paid to the rank of the parties; and unsuitable matches are guarded against, by the infliction of the most rigid penalties. Farther, when the son or daughter of a family enters into the state of wedlock, they have no right to appear before their parents during the first year, or till the birth of a child. It is not till the same period has elapsed that a daughter obtains her full marriage portion; but on this occasion, a visit is paid to her by her father, who takes off the cap she wore when a virgin, with his own hands covers her with a veil, which from that time becomes her constant head-dress, and, finally, discharges what had hitherto remained unsettled of her dowry.†

---

[*] A different account is, that girls are educated at home by their mothers; that it is only the male-children who are thus committed to the guardianship of strangers; and that, even with respect to them, the father, at their birth, does no more than choose a person who is, at a future period, to discharge towards them the duties of preceptor. When a year old, it is said, they are presented with playthings, and with arms; and if they appear to prefer the latter, this event is celebrated with great rejoicings. At the age of seven, or, according to others, of twelve, they leave their fathers' houses for those of the appointed preceptors, by whom they are taught to ride, to use arms, to steal, and to conceal their thefts. The epithet thief, it is remarked, is not here a ground of reproach, otherwise than it implies detection. Indeed, dexterity in the arts of pillage is the great object aimed at in education. From the simpler elements of petty pilfering, the youth are therefore trained by degrees, and led on to the practice of more considerable and dangerous robberies, and return not to the paternal mansion, till their cunning, address, and strength, are esteemed to be in some degree perfected. The preceptor is recompensed, for the trouble and expence at which he may have been in their education, by nine-tenths of the booty which they may have acquired during the period they were under his tuition.

[†] Sometimes the person pitched upon to receive that trust, is a prince of another family.

[‡] The custom of committing, in this manner, the education of children entirely to strangers, has been supposed to be peculiar to the Circassians. But every where amongst the mountaineers of Caucasus, who universally subsist, in a greater or a less degree, by the practice of robbery, similar objects, at least, are had in view in the education of youth. It is said, that the system of tuition alluded to, is persevered in amongst the Circassians, chiefly with the design of preventing the bad effects to be apprehended from the excess of parental indulgence. At the same time, it is to be observed, that as the education of a child renders the preceptor, in effect, a kind of adopted father, and as this nation is extremely vindictive, a person who has killed any relative of a family, sometimes endeavours to steal away a child belonging to it, for the purpose of educating him, that, by this means, a door may be opened for a reconciliation. It is farther stated, that a vassal contrives to steal, upon occasion, and to educate the son of his prince; a he has no

Matrimony.

Between husbands and wives, particularly during the earlier part of their marriage-connection, there is observed a system of affected politeness, equally remote from reason and nature. An uncommon degree of reserve, indeed, especially among persons in the higher classes, seems all along to be maintained by the parties joined together by so very intimate a bond of union.‡ The origin of the peculiar custom prevalent here, in this respect, as well as of the principle of committing the education of children to strangers instead of their own parents, cannot apparently be traced to any distant nation. But if they are supposed to have been, from an early period, prevalent in Mount Caucasus, a reference to them may be of use in accounting for the fabulous descriptions which have reached us of the Amazons and Gargarenses, nations whose local position assigned by the ancient geographers seems to correspond with sufficient accuracy to that of the countries now occupied by the Circassians.

Language.

The language spoken by this people has been said to be common to them with the other neighbouring Tartars. In the different parts, however, of the great chain of mountains which bears the appellation of Caucasus, there is reason to believe that there is considerable variety of language. Few of the present inhabitants of Kuban Tartary can converse with any of the Circassian tribes. Indeed Pallas thinks it probable, that the Circassian bears no affinity to any other language; and that, according to report, their princes and usdens speak a peculiar dialect, which is kept secret from the common people, and used chiefly in their predatory excursions. The latest accounts of that country state, that those of the inhabitants with whom there had been found any opportunity of holding conversation, spoke in a dialect so harsh and guttural, as was by no means pleasing to the ear. The higher orders here are said to be not unacquainted with the Russian tongue. It appears, from a vocabulary of the languages or dialects of the Caucasian nations, published by Mr G. Ellis, that many of the words in use in these parts are the same as those of the uncivilized inhabitants of America; whence, it has been conceived, an argument may be drawn in favour of the opinion advanced by Hornius and others, that America was originally peopled by colonies from Asia, particularly from Scythia or Tartary. As there are no written characters in use among this people, those who would write in their language are obliged to employ for this purpose the Arabian letters.

Music.

The favourite musical instruments of the Circassians is the camil, a kind of flute, made commonly of silver or some other metal. It is about two feet in length, having only three finger holes towards the lower extremity of the tube. The mode of blowing this instrument is remarkable. A small stick is placed in the upper end of the flute, which is open at either extremity, and, being drawn out to the length of an inch, is pressed by the performer against the roof of his mouth. It is difficult to conceive how tones may be produced in this manner, as the performer's mouth is kept open the whole time, and he accompanies the notes with his own voice. From the violent straining of every muscle in the countenance, it would appear that the playing on this instrument is a work of great difficulty and labour. The sounds produced resemble those of the bagpipe.

Dancing.

The dances of the Circassians do not resemble those of any other nation. Ten, fifteen, or twenty persons, all standing in a line, and holding by each other's arms, begin lolling from right to left. They lift their feet as high as possible, to the measure of the tune; and the uniformity of their motions is interrupted only by sudden squeaks and exclamations. It should seem that the situation of the performers in the middle of the row must be extremely uneasy, yet even these, squeezed as they are from one side to the other, testify their joy in the same manner as the rest. After some time there is a pause, when a single dancer, starting from the others, prances about in the most ludicrous manner, but exhibiting two steps which may be assimilated to the movements of a dance as practised among the European nations. The first consists in hopping on one foot, and touching the ground with the heel and toe alternately of the other: the second, in hopping on one foot, and thrusting the other before it, so as to imitate the bounding of a stag.

The religion of the Circassians is Paganism; for

---

doubt that, by his success in this attempt, he will ensure his own advancement to nobility. The point that is universally agreed upon, is, that wherever and by whatever person the office is discharged, the child must at least be educated at a distance from his father.

* This is the case particularly at the little rejoicings which take place here at festivals. Before a ball, the men show their activity and address in a variety of military and other exercises; and the most alert on these occasions, have the privilege of choosing the most beautiful partners.

† It is customary in Circassia, that a bridegroom, previously to his entering into the married state, should make to the relations of the bride a present of armour, chiefly of a coat of mail. This is considered as a sort of purchase-price given for the bride.

‡ In point of fact, it may be truly said, that, in Circassia, a husband is of all the world the person whose intercourse, ever with his own wife, is the most restrained and fettered, by a singular enough custom, to a dull and uninteresting formality. Indeed, if a husband will permit a stranger to see his wife, it seems to be a fixed point, that he himself should not accompany him; and so far is this article of good manners carried, that when any one comes to see the wife, the husband goes out of the house. In the manner even of constructing the houses, it may be added, that there is a distinct adaptation of them to the same modes and habits of life; they consist of two huts, of which one is appropriated to the husband and to the reception of strangers, the other to the wife and family, and the court which separates these two parts of the dwelling is surrounded by a palisade. It is said, that this artificial manner of living, is not in Circassia productive of any licentiousness of manners. The Circassian women, on the contrary, with all their charms, and in spite of such temptations, as it were even sedulously thrown in their way, are yet noted for their chastity; whether this estimable part of their character is to be considered as the consequence of their natural disposition, of a regard to reputation, or of the wish to make a generous return for the confidence reposed in them by their husbands. In other respects, the women of this country participate in the general character of the nation. They take a pride in the courage of their husbands, and reproach them severely when they have sustained a defeat. Farther, it is they who polish and take care of the armour of the men.

§ See his *Memoir of a Map of the Countries comprehended between the Black Sea and the Caspian*, 1788.

Religion.

though some of them were formerly Christians, and others Mahometans, and the rite of circumcision is still in use here, they have neither priests, Alcoran, or mosque, like other Mahometans. Every one offers his own sacrifice at pleasure, on certain days, however, appropriated to that purpose, more, indeed, from custom than in consequence of any positive command. The most solemn sacrifice is that of a he-goat, which is offered upon occasion of the death of near friends. At such times, both men and women meet in the field, to be present at the celebration of the solemnity. Then, the animal being killed, it is flayed, and the skin, with the head and horns, is stretched upon a cross at the top of a long pole, placed commonly in a quickset hedge, to keep the cattle from it. Near to this spot the sacrifice is offered, by boiling and roasting the flesh, which is afterwards eaten. When the feast is over, the men rise, and, having paid their adoration to the skin, and muttered over certain prayers, they are left by the women, and conclude the ceremony with drinking a great quantity of *aqua vitæ*, which generally leads to a quarrel before their final separation. The state of degradation in this country, as to virtue and morals, is at least fully in proportion to the smallness of the attention paid in it to religion. The Circassians are accused of frequent perjuries, and violation of treaties. Oaths taken on the Bible, or the Koran particularly, it is said, they break without scruple. Yet there are certain forms of oaths, it is alleged, as well as certain places, supposed to be the remains, or spots in the neighbourhood of the remains, of Christian churches, which are more respected amongst them, and which ensure their fidelity. The courage of this people, great as it is, it may be remarked, is not proof against religious terrors; and, like all barbarous nations, they believe, that what is called accident, may be influenced in respect to the manner of its occurrence, or retarded or prevented through the use of particular ceremonies.

Tribes.

There are several distinct tribes of the Circassians. The designations of the principal of them are the following: The Kabardines, the Beslene, the Temirgoi, the Pshedukhs, the Hattukai, the Shani, the Shagaki, and the Mukhoshians. These tribes, occupying respectively their particular territories, and subject to the authority of their own rulers, agree in the main as to the leading outlines in their condition and character. Generally, they apply themselves more or less to agriculture, and to the rearing of cattle. Some of the tribes are wealthy and powerful. The resources of others are less considerable. In various degrees they are addicted to robberies, and frequently are involved in broils, either amongst themselves respectively, or with one another. The amount of the population of this whole country it is difficult accurately to ascertain. From some data, however, on the subject, there seems reason to believe, that the Kabardines alone can bring into the field a power of about 10,000 privates, and 1500 usdens. The Temergoes, with their allies of Beslene, Mukhoshians, and Pshedukh, are stated to possess, when united, a force of at least 5000 effective men. When to these numbers is added the population of the other tribes mentioned, it may be readily understood how much, but for the prevalence of divisions among themselves, the neighbouring powers would have occasion to dread their too near approaches. Neither is this danger grounded solely on the consideration of their numbers. They are a gallant and warlike people, and are bound by every tie to follow their prince into the field, and zealously and faithfully to yield an implicit obedience to his commands.

It is obvious how very formidable this people would become, were they ever to be united under the government of one chief. A nation of mountaineers, however, it is to be observed, who are forced, for the sake of pasture and water, to fix themselves upon the banks of the detached rivers, soon forget their origin, and are divided into separate and hostile tribes. This is so much the case with the Circassians of the Cuban, and their power is therefore so inconsiderable, that they are scarcely known even to the Russians, but by the general appellation of Cuban Tartars, in which they are confounded with their neighbours the Archaseans and the Nagair.

Kabardines.

The branch of this nation most interesting to the historical inquirer, is that usually called the Great and the Little Kabarda; and this, both in respect of its own importance, and of its varied intercourse of war or peace, particularly with the adjoining great empire of Russia. The Kabardines, it is to be observed, hold themselves to be of Arabian origin; and not improbably they are the remains of the armies formerly sent by the caliphs against Caucasus; others deduce them from the Mamelukes. General tradition, confirmed by still subsisting names, shews, that they formerly inhabited the Crimea. At what period they extended their possessions along the banks of the Kuban, and in the country of the Beshtan, cannot, at present, be easily discovered. It is probable that they were first subject to the rulers of Georgia, together with a considerable part of the Caucasus. After the separation of that kingdom in the sixteenth century, and particularly after the defection of the provinces of Mingrelia, Guriel, and Abasa, they became subject to the Khan of Crimea. In the same century they submitted to the protection of the Czar, Ivan Vassilizvitch, who, about the year 1560, married a princess of their country. In the 17th century they again acknowledged the sovereignty of the Crimea; and when, in the beginning of the 18th century, they attempted to shake off this yoke, the Khan penetrated into their territory, and drove them before him to the mountains extending towards the source of the Baksan, where they fortified themselves with stone mounds erected in the defiles, which, to this day, have retained the name of the Crimean walls. Having, by a piece of the most nefarious treachery, extricated themselves from the dangerous situation in which they were thus placed, they felt the necessity, in order to avoid the consequences, of soliciting anew the protection of Russia. While they recognise the superior authority of this power, the Kabardines have continued to live in a state of immediate submission to their native princes, the three families of which rank acknowledged amongst them, they pretend have all been derived from the same source. The nobles, or usdens, are divided into the ancient equestrian nobility, and such as hold that dignity from others, or the usden of usden. The third class is that of the vassals, or people, some of the circumstances in whose condition have already fallen under observation. A certain number of these is allotted to, and placed under the jurisdiction of each princely family. In these divisions respectively, the eldest individual is considered as chief of the family, judge, protector, and father of all the vassals attached to it. Out of this order, the princes have the privilege of raising whom they please to the rank of nobility, but they are equally empowered to deprive them, if they see fit, even of every thing that they possess.

History.

The Circassians are understood to have been descended from the Alanians, who settled on the northern side of the Caucasus soon after it had been occupied by the Yazamates. By them, or by races collaterally related to them, possession was gradually taken of the southern regions adjacent to the Kuban. During the empire of the

Chazares, the Byzantine emperors appear to have exercised a sort of paramount supremacy over this nation. The Circassians, however, remained truly independent in the upper regions of the mountains, and were still in possession of the whole eastern coast of the Sea of Azof as far as the Don. They rendered themselves masters of Kertsch in the Crimea, made frequent incursions into that peninsula, and into other European countries, formed the basis of the then rising Caucasian tribes, and founded a famous dynasty in Egypt. They continued equally unsubdued amidst the mighty changes every where effected about the close of the 14th century by the arms of the great Timur, and afterwards in face of the incursions of the Ottomans. While in the middle of the 16th century, as has been already stated, they, or a principal part of them, acknowledged for a short time the authority of the Czar Ivan II. of Russia, they yet about the same period formed, in conjunction with some of his native subjects, the state of the Don Cossacks, retaining possession of all the islands of the Lower Kuban, the whole of its southern banks, and the regions contiguous to the Euxine. Subsequently to that era, this people, or portions of them, have, in respect to dependence, been in the state of vicissitude, of which some of the steps have been already noted, holding at one time of the khan of the Crimea, at another of the Porte, at another of Russia. Ever since the conquest of the Upper Kabarda by Ivan II., the sovereigns of the latter empire have been accustomed to style themselves lords of the Kabardinian countries of the Circassians and mountain princes. The reality of power, which has been far from being ever since connected with this sounding title, has, in recent times, been in some degree attached to it. Between the years 1740 and 1750, the princes of the Great and Little Kabarda several times took the oaths of fealty to Russia. And the separation of the Asiatic territories, usually comprehended under the general appellation of Circassia, having in 1783 been recognised to be made by the river Cuban, all the districts and stems in those parts, situated in the islands of the Lower Cuban, along the whole southern shore of that river up to its source, and in the regions bordering on the Euxine as far as Auchasia, have, since that period, been held to be in a state of proper subjection to the Russian empire. The Circassians in both the Great and Little Kabarda, are reckoned among the vassals of that power.

This division of that people being the most considerable of all the tribes on the northern side of the Caucasus, the imitation of their manners has been so general among their neighbours, that, in this respect at least, all these tribes may be looked upon as the component parts of one great nation. Some of the traits principally characteristic of this people have already been mentioned. The following also are deserving of notice.

Government.

No prince among the Circassians can be a landholder. The only property of those of this rank consists in their arms, horses, slaves, and the tribute which they can extort from the neighbouring nations. The person of every prince is esteemed sacred. This, however, is the only distinction of birth unaccompanied by personal merit. The greatest honour which a prince can gain, is that of being the first of his nation to attack or to restrain an enemy. In time of peace, the princes are not distinguished from the nobility, or even from the peasantry, their manner of living being the same, and their houses, or other accommodations, being little superior to theirs. The rank of nobility is founded in part at least, and, in some instances, on an elective title; it being in the power of the prince to raise at his pleasure to that dignity, persons from the inferior classes of society. The nobles are the officers of the prince, and are entrusted with the execution of the laws. On important occasions, he calls a council of those of this rank, and the resolutions that are agreed on are communicated through them to the people. In the general assemblies of the people, it is equally their part to endeavour to gain the public assent to the measures proposed by the princes. The people, as well as the usdens or nobility, are, or may be, proprietors of lands. It is somewhat singular, that the princes who have themselves no property of this kind, yet claim, and sometimes attempt to exercise, the right of seizing the whole of that which belongs to their vassals. It seems equally an inconsistency, that, under these circumstances, a vassal when he thinks himself aggrieved, should have it in his power to transfer his allegiance from his native to any other prince. It is plainly the effect of this last arrangement, to render the former in a great measure nugatory, as, in consequence of it, it not only becomes necessary for a prince to endeavour to gain the affections of his vassals, if, through their exertions in the field, he would cherish the hope of acquiring for himself either greatness or wealth; but it is, in reality, through a persevering attention only to accommodate himself to their wishes, that he may reasonably expect to retain for any length of time over them, even the shadow or any appearance of authority.

Laws.

The Circassians do not appear to have any written laws; but they are governed by a kind of common law, or a collection of ancient usages. On great occasions the whole nation is assembled, when such measures as are deemed expedient being proposed by the eldest of the princes, they are first discussed amongst the usdens, afterwards by the deputies of the people. Their deputies are generally of the older men of the nation, who possess ordinarily with their constituents a greater influence than is attained to even by the prince himself. When a proposition thus introduced and carried forward has been finally acceded to, it is, for the sake of the greater security, commonly confirmed by a solemn oath taken by the whole people.

It is agreeable to the customs of the Circassians, that, at their meals, the whole families, some of the parts of which are at other times little together, should assemble severally to partake in common of their necessary food. Hence it is, that here, as among the Tartars, each village is usually reckoned at a certain number of kettles. The manner of living among this people is extremely simple. One part of their food consists of a little meat, either the flesh of the game in which the country greatly abounds, of beef or mutton, or what it is said is preferred to all others, of the flesh of a young horse. Together with this, they make use of some paste made of millet, or of thin cakes of barley meal baked upon the hearth, and which are eaten always new. Their usual drink is water, a kind of beer made from millet fermented, or mare's milk, from which latter there is here distilled a spirit, as amongst most of the Tartar nations. The Circassians do not uniformly allot stated hours for the refreshments of the table, or sleep, but upon occasions indulge in them irregularly, as inclination or convenience dictates. When the men make excursions into an enemy's country, they will even pass several days and nights successively without sleeping, and, at their return, they devote as much time to repose as they had thus been withheld from that gratification. In eating, it is the practice here to sit cross-legged on the floor, the skin of some animal serving as a carpet. The custom of smoking tobacco is universal among men, women, and children: whence, as in other Tartar countries, that is the most acceptable commodity which a traveller can carry with him into these parts.

It is the practice in Circassia for widows to tear their hair, and to disfigure themselves with scars, in testimony of their regret for the loss of their husbands. It was formerly usual for the men also, to give way to similar expressions of sorrow; but of late they have grown much more tranquil under the loss of their wives, or of other relations.

The chief city of Circassia is Terke. The prince who resides here is allowed a guard of 500 Russians, but none of his own subjects is suffered to dwell within the fortifications. Ever since the time that this country was subdued by Russia, not only governors and garrisons of that nation have been appointed to all places of strength in it, but it has been provided from the same quarter with its magistrates, and with priests for the exercise of the Christian religion. In subordination to the supreme authority of Russia, the Circassian Tartars acknowledge indeed their own princes, lords, and judges; but these all are obliged to take the oath of allegiance to his imperial majesty; they administer justice in his name, and, in matters of importance, not without the presence of the Russian governors. See Tooke's *View of the Russian Empire*; Pallas's *Journey through the Southern States of Russia in* 1793-4, &c; and Clarke's *Travels in Europe, Asia, and Africa*, vol. i. (K)

CIRCENSIAN GAMES, originally called *Consualia*, were dedicated to the god Consus, and were established by Romulus at the rape of the Sabines. After the Circus was built by Tarquin the Elder, they received the name of Circensian games. The celebration of these games began on the 15th September, and continued five days; and they consisted in feats of leaping, boxing, wrestling, racing both in chariots and on foot, and throwing the javelin and quoit. (*j*)

CIRCLE.

ASTRONOMICAL CIRCLES having now entirely superseded the use of the quadrant, and become the principal instruments of almost every observatory, we feel ourselves called upon to devote a considerable portion of our work to the explanation of the principles of their construction, and of the most eligible methods of using them to advantage.

The astronomical quadrant is so simple in its construction, and one instrument of this class differs so little from another, that the description of one will easily render intelligible the construction of all the rest. It is not so, however, with the astronomical circles. So very various have been the views and conceptions of the different artists who have been employed in these instruments, and perhaps even of the same artist at different times, that, except in circles of small dimensions, we believe that two have never yet been made alike. Hence we find no small difficulty in selecting such examples as may be reasonably expected to continue of universal and permanent utility.

Circle made by Ramsden for Piazzi.

The circle of Piazzi, at Palermo, constructed by Mr Ramsden, was the first large instrument of modern construction, and has become justly celebrated in the history of practical astronomy; but it owes its celebrity certainly more to the industry and sagacity of the observer into whose hands it has fortunately fallen, than to the accuracy or soundness of the principles on which it is constructed; for though it contains numberless examples of beautiful invention and contrivance, yet upon the whole it is an instrument that no judicious artist would ever wish to make again: We shall not therefore detain the reader with any particular description of it, but shall only observe, that it is an altitude and azimuth instrument. The diameter of the vertical circle is five feet. The plumb-line by which it is adjusted, referring to two fixed points in the limb of the circle, cannot be examined at the moment of observation: From this cause, and from the effect of expansion, to which, from its faulty construction, it is much exposed, a single observation cannot be relied on, nearer than to five seconds, though a mean of several will probably be much within that limit.

Wollaston's transit circle made by Carey.

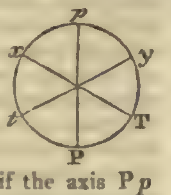
In the year 1793, Mr Wollaston published a description of a circle made for him by Mr Carey, and which he very properly terms a *Transit Circle*. This instrument had an accidental defect, (the axis having been made rather too slender,) but with this exception the instrument was a very good one. The beauty of the workmanship of Carey's instruments cannot be surpassed; and the whole of this instrument was better imagined, than the large one above noticed of Ramsden. It was not, however, intended to turn freely in azimuth, but, on the contrary, principally designed as a transit instrument, which intention appears to have been accomplished with the greatest precision. For this practical success of combining two instruments in one, astronomers are certainly much indebted to Mr Wollaston. Piazzi, in enumerating the advantages of a circle, mentions this combination: but certainly his circle would be a very imperfect transit instrument, or more properly speaking, it would be absolutely useless in this capacity. Carey has constructed several of these instruments, which perhaps would be all improved by a very slight alteration in the mode of applying the plumb-line. His method is nearly similar to Ramsden's above noticed, and subject to the same objection, as will be better understood when we come to treat of the more detailed construction of particular instruments. It is in this circumstance (among many others) that Troughton's instruments differ from Carey's and Ramsden's. The principle of these two methods is thus shortly described by Mr Pond, in the *Philosophical Transactions* for 1806.

Ramsden's method of applying the plumb-line.

In Mr Ramsden's method, two points are taken on the limb of the circle; and when these are brought into a given position, by means of a plumb-line passing over them, the microscope or index is made to coincide with the zero point of the divisions. By this method the error in collimation remains constant; and if the adjustment is by any accident deranged, it can easily be rectified, and there will be no absolute necessity for frequently reversing the instrument; so that this method seems well adapted for large instruments, particularly if placed on stone piers. But it is liable to this defect, that the adjustment cannot be examined at the moment of observation; and if any change should take place in the general disposition of the frame-work, the observation will be erroneous, without the means of detection. It was probably to avoid this inconvenience, that Mr Troughton in most of his instruments, particularly if they were intended to move freely in azimuth, has preferred the other method.

Troughton's method.

In this case, the plumb-line is attached to one of the pillars which support the microscopes in the way above described; and it has no reference to any fixed points or divisions on the limb of the circle, but only insures a similarity of position in the index for each position of the instrument; and provided that the plumb-line apparatus was free from all danger of derangement, this would be sufficient. This verification may perhaps be rendered more intelligible, by considering that a circular instrument, in whatever manner its vertical axis be placed, indicates, by a double observation, the angle which the object makes with the axis, round which the whole instrument has revolved in passing from one position to the other. For let P*p* be the axis, T*x* the telescope in one position; it is evident that in turning the instrument half round, *ty* will then be the position of the telescope, P*x* being equal to P*y*. The arc *xy* which the telescope passes through to regain its former position, is the quantity really given by the instrument; and if the axis P*p* be vertical, half this quantity is the true zenith distance of the object. Now the intention of Mr Troughton's verification is to insure a vertical position to the axis P*p*.



For instruments which rest on moveable pillars, and turn freely in azimuth, this method is much to be preferred; but it is not without a considerable defect, for if by any derangement in the plumb-line apparatus, the error in collimation be changed, it cannot be restored with certainty to its former position, so that sometimes a very valuable series of observations may be lost, for want of a corresponding one to compare with it.

Circle made by Troughton for Count Bruhl.

It was in 1792, after having made several smaller ones, that Troughton constructed a circle for Count Bruhl. The observations made with this instrument were very few, but exceeded in accuracy any that had been made before. The diameter of this circle was only two feet, but we are strongly inclined to believe that it exceeded in accuracy the five feet circle of Piazzi.

Ramsden's equatorial.

The equatorial instrument constructed by Ramsden for Sir George Shuckburg, properly belongs to the class of astronomical circles It will be more fully noticed under the article OBSERVATORY. Few observations have been, we believe, ever made with it. Indeed it is a waste of so very capital an instrument to place it in the equatorial position, because meridian observations will always *ceteris paribus* be better; and in practical astronomy, a *second best* method is absolutely of no use. This valuable and superb instrument has lately been presented to the Royal Observatory of Greenwich by the Hon. Mr Jenkinson, and is intended to be used both in the vertical and inclined position; and as an altitude and azimuth instrument, there can be no doubt but it will prove a most valuable acquisition.

Troughton's equatorial.

An equatorial instrument, by Troughton, of which the vertical circle was 3½ feet in diameter, was erected at Armagh; and Dr Hamilton's observations made with it were inserted with Mr Pond's, in the Transactions of 1806.

Several other circles were made by Troughton of different dimensions, varying considerably in the subordinate contrivances, but much resembling each other in their general principle. Mr Wollaston describes a very perfect instrument, by Troughton, of this kind, (not very unlike the one hereafter treated of,) in the Appendix to his *Fasciculus*; and gives some excellent directions to less experienced observers, which we shall avail ourselves of before we conclude this subject.

Circle made for Mr Pond by Troughton.

Mr Pond's catalogue of stars, which first demonstrated the defect of the Greenwich quadrant, was deduced from observations made with a circle constructed by Troughton, 30 inches in diameter, and is minutely described in the *Philosophical Transactions.* It is exactly similar to a smaller one now possessed by General Brisbane, and of which we have given a representation in Plate XLV.., and a description in the article ASTRONOMY, vol. ii. p. 727.

Circle made for Mr Groombridge by Troughton.

One of the most perfect instruments of the kind is that in the possession of Stephen Groombridge, Esq of Blackheath. It is a transit circle placed between two piers, made according to the idea suggested by Mr Wollaston. The four microscopes are placed in the horizontal diameter, two on each side, the instrument being on both sides divided. From observations made with this instrument, a very valuable paper on astronomical refractions has been already communicated to the public.

Circle made for the Dublin observatory by Ramsden.

The largest astronomical circle that has been yet constructed, is that belonging to the observatory of Dublin. The vertical circle is eight feet diameter. It was begun by Ramsden, and finished by his successor Mr Berge. It was erected about the year 1807. We have not seen any printed description of it, nor have many observations made with it yet been published; but we understand that the learned astronomer, Dr Brinkley, to whose care it is now entrusted, is perfectly satisfied with its performance; and it is with this instrument that he has been able to infer the apparent annual parallax of Lyræ, which he estimates to be between two or three seconds.

Circle made for General Brisbane by Troughton.

To the above, we may add a very beautiful two feet circle, in the possession likewise of General Brisbane, and which was actually the model of the six feet mural circle erected last summer at Greenwich. It differs in principle from all those above mentioned; and though it is not in our power at present to describe very minutely the mechanism of either of these instruments, of which no account has yet been published, we are nevertheless enabled to explain some of the more striking peculiarities in their construction.

The grand mural circle made for the observatory of Greenwich by Troughton.

The Greenwich mural circle was placed on its stone pier in the month of May 1812, and the observations for publication commenced the 11th of June. In the last volume of the Transactions for the present year (1813), the astronomer-royal has communicated his observations of the summer and winter solstice of 1812, and likewise a catalogue of some of the principal fixed stars, deduced from nearly 2000 observations. From what little is said of the construction of the instrument, it may be collected, that no use whatever is made either of level or plumb-line, but that the position of the polar point on the instrument is found by assiduous observation of the pole-star; and that the position of this point on the instrument is inferred, by comparing the observed places with the real places of a certain number of standard stars, previously determined by the instrument itself. By this method the astronomer-royal observes, that the position of his instrument may always be known to within a tenth of a second, a degree of precision which no level or plumb-line can ever be expected to obtain. We shall have occasion to insert this valuable catalogue, and to recommend the adoption of a method somewhat similar, when we shall have to explain the different uses of Borda's repeating circle, which we have hitherto omitted to notice, certainly not from its inferior importance, but because we have confined ourselves chiefly to the instruments of our own country. And as we propose to give a very minute account of the construction of this instrument, we shall only at present remark, that in France it seems to have superseded the use of every other astronomical instrument, for measuring either the zenith distances of heavenly bodies, or the angular distances of terrestrial ones.

This brief introduction embraces all the principal astronomical circles which we know of in fixed observatories. It is, however, our intention to give, under the article OBSERVATORY, a more detailed account of some of them, particularly Mr Groombridge's transit circle, and the mural circle now in use at Greenwich. For we mean here to confine our descriptions, &c. to the three distinct classes of portable circles, namely, the *Reflecting Circle*, the *Altitude and Azimuth Circle*, and the *Repeating Circle*; and beginning with the reflecting circle, we shall endeavour to trace its progress through the principal improvements which it has undergone, from its first invention down to the present time.

CHAP. I.

On the Reflecting Circle.

Reflecting circle.

THE instrument which bears the appellation of reflecting circle, is of the nature of Hadley's quadrant, and is built upon the same foundation; and, for the present, we shall consider our readers as acquainted with that well known instrument, a full account of the principles, properties, and use of which, shall be reserved, in order to be introduced under its appropriate title.

Although there are few purposes in practical astronomy and surveying, to which this kind of instrument may not be advantageously applied, yet it was originally constructed for, and has been chiefly used in making lunar observations, for finding the longitude at sea. The late Professor Mayer of Gottingen, the ingenious and laborious astronomer who first furnished tables for that purpose, seems to have judged well of what kind of instrument would ultimately be used, to effect the best practical solution of the lunar problem. Agreeable to this idea we find, that when he transmitted to England his solar and lunar tables, they were accompanied by drawings, and a description of the first reflecting circle, and were published by the British Board of Longitude in the year 1770.

As it is not our intention to extend this article to an unnecessary length, we shall, without farther introduction, proceed to a description of Mayer's instrument.

SECT. I. *Description of Mayer's Reflecting Circle.*

Mayer's reflecting circle.

PLATE CXLIV. Fig. 1.

Fig. 1. of Plate CXLIV. is a plan of this circle. Its chief part is a cross, surrounded by a circular limb all in one piece. Immediately above this is an index A, to which is affixed the telescope and horizon-glass. Still higher, another index B carries the central glass. Both A and B move freely round upon a pin fixed in the centre of the circle, quite independent of each other, and both of them apply close to the border of the circle, for the purpose of reading off its divisions. From the form of the exterior ends of the indices, one would imagine that the limb was intended to be divided by diagonal lines, but as the vernier was known at that time, it is probable, that no instruments were ever constructed in this respect like the figure. At the time the circle was proposed by Mayer, the art of dividing instruments was in a very rude state, and to render bad dividing of little or no consequence, was the aim of this particular construction.

It will be presently seen, that, with this circle, as many observations as we please may be successively made from point to point upon the limb, without reading off any more of them than the accumulated angle, having previously indeed noted the point at which we commenced. This is a very different thing from taking many observations with a sextant or quadrant, when the angles that compose a set being all read off nearly upon the same part of the arc, will most probably be all affected with nearly the same error. It is also very different from making many unconnected observations with a circle, where the beginning and end are read off in each; for, in this case, every angle will be charged with two errors; whereas, when taken in the manner which the nature of this instrument requires, no more than two errors are charged upon the amount of observations, however often these may have been repeated.

To shew more particularly how this is performed, it will be necessary to return to our Figure. There the different parts are represented, as when the index and horizon glasses are parallel to each other; in which position, an object will be seen in the telescope through the transparent part of the horizon-glass, in exact contact with its own doubly reflected image; but by moving the index B towards the telescope, the reflected image will pass along to the left, and being followed by the instrument, may be made to coincide with any object seen directly on that hand; and now the index B would mark the distance between the reflected and direct objects, but it is totally unnecessary, and would even counteract the advantages of the instrument, to pay any attention to this point upon the circle. Instead of this, let the index A be carried forwards until a new point of parallelism is found, by making an object coincide with its own reflected image as at first. This being done, take the angle over again, by moving the index B towards the telescope, and following the motion of the reflected image to the left. In this manner proceed, by alternate observations for parallelism of the glasses, and angular distance of the objects, until you have made a sufficient set. By this beautiful contrivance, a small instrument is, as far as dividing may be concerned, rendered at least equal to a large one without it; but as the telescope, by which the contacts are made, is necessarily of small power, large instruments in this respect seem to have the advantage; yet, as many observations are required to make a set, the error arising from imperfect contact must be considerably diminished on the well known principle of taking means.

Improvements by Bird.

Professor Mayer proposed, that his new instrument should be 16 inches diameter; and for the purpose of relieving the arm of the observer from the weight of so heavy an apparatus, recommended that it should be supported by a staff, which should rest upon the ground or deck. Bird, who probably made the first of these instruments, improved upon that idea. He made the staff communicate with a belt, which buckled round the loins of the observer. The staff was double, being composed of two sliding tubes. These moved one within the other, for the purpose of adjusting the height of the circle to the eye of the observer, and by the help of a *ball and socket* attached to the centre of the instrument, he was enabled to accommodate its plane to the position of the objects. Bird also applied darkening glasses to the reflecting circle, and gave it every useful appendage which Hadley's quadrant had borne before. In particular it should be mentioned, that the telescope was attached to the index A by two double levers, which acted exactly in the same manner that the single ones do in the common parallel ruler. On these levers the telescope rose and fell, respecting the line of separation between the silvered and unsilvered parts of the horizon-glass. A consequent backward and forward motion necessarily took place. This is a much better contrivance for regulating the brightness of the two images, than that which was adopted afterwards for the same purpose by Borda. It is a curious circumstance, that Bird divided his circles into 360° instead of 720°, as the nature of all reflecting instruments require; whence it became necessary to double the angle read off in a single observation, and in continued ones, to divide the accumulated angle by only half the number of repetitions.

It may be considered an unfortunate circumstance for the credit of the reflecting circle, that Bird was its original maker; for the correctness of his dividing, determined Admiral Campbell to neglect the repeating principle altogether, which he deemed a troublesome mode of observation, and to use a single portion of the limb. He then saw, that the arc of the octant ought to be extended to a sextant, so as to measure 120 or more degrees, and represented to the Board of Longitude, that a sextant, the radius of which should be double that of the circle, would be equally manageable at sea. He was ably seconded by Bird in these speculations; and such was the opinion of astronomers and others, concerning the judgment of these two individuals, that, in this country, the sextant was immediately adopted for the nicer nautical purposes, to the exclusion of the octant and circle which preceded it.

It has just been said, that the accuracy of Bird's dividing caused the reflecting circle to be laid aside in this country; and we may add with equal truth, that the rude state of that art in France, occasioned that instrument to be adopted there.

SECT. II. *Description of Borda's Reflecting Circle.*

Borda's reflecting circle.

About the year 1775, the justly celebrated Chevalier de Borda, turned his thoughts to the improvement of the reflecting circle of Mayer, and, after 12 years application to the subject, gave his labours to the public in an excellent pamphlet, which appeared at Paris in 1787. In this work, the chevalier minutely describes the former construction, gives a particular account of his own improvements, as well as ample instructions for using the instrument, and accompanies these, with complete directions for finding the longitude by the lunar method, together with new rules and tables for this and other nautical purposes.

PLATE CXLIV. Fig. 2.

Fig. 2 of Plate CXLIV. is a representation of Borda's circle, which, upon a comparison with the figure of Mayer's, may probably at first sight seem to exhibit a trifling difference for a work of 12 years; but when we come to comprehend the effects that proceed from these alterations, we must acknowledge, with satisfaction, that the time was not spent in vain.

The great objection to Mayer's circle was, that it required two operations in order to obtain one result; namely, one for the parallelism of the glasses, and another for the angular distance of the objects. Borda removed this inconvenience in the neatest manner possible; and in doing this, gave the instrument new and useful properties. On looking at the figures, it will be seen that the telescope is drawn back, so that no part of it extends beyond the index-glass; and, that the horizon-glass is carried forward nearly to the opposite limb: these alterations, simple as they are, accomplish his greatest improvement. We have now two ways of making observations; for reckoning from the point of parallelism as the glasses are represented in the figure, we can carry the reflected image either to the left, by moving the index A forwards, or to the right, by moving the index B forwards; for the incident rays may now fall on the index-glass through a long range, either above or below the horizon-glass. The point of parallelism is of no more use, for we are now enabled to observe, at each step of either index, the correct double angular distance. Borda calls half of this distance an observation to the right, the other half, one to the left, and both together, he calls a crossed observation: he calls it crossed, because the image of the reflected object crosses the point of parallelism. To use the instrument, it is best, in the first place, to set the index B at *zero,* and then by the motion of A to make the reflected image of the object on the left, pass beyond the point of parallelism, following it with the circle until it arrives at, and coincides with, the object on the right; all this is preparatory. Looking now to the right, bring the glasses parallel, by moving B forwards; but pass that point, following the reflected image until it comes to the object on the left; the double angular distance will now be marked by B, but this is not yet to be noted. Perform a similar operation by the index A, reflecting from left to right, and a second by B, reflecting from right to left: proceeding in this manner, by alternate motions of the indices, until you have completed a sufficient set. The whole number of degrees now read off at B, divided by double the number of times which that index was carried forwards, will give the angle sought; and where the observations are connected with time, as in taking lunar distances, that angle will correspond with the mean of the times at which the contacts were made. It should be remarked, that had the index A been read after the preparatory step, another result might have been obtained from it; but it would have been required, that the set had concluded with a motion of A, or else that the crossed observations had been respecting it, reckoned one less in number.

For the sake of simplicity, these directions have hitherto been carried on, as if the two objects could be either of them reflected one to the other; but this will seldom be practicable; and it therefore becomes necessary, that the brighter of the two should be reflected to the fainter, as the sun to the moon, the moon to a star, &c. To make this appear, let the indices be supposed to stand as they did on completing the preparatory step; and suppose the objects to be the sun to the right, and the moon to the left; make the first observation by reflecting the sun beyond the point of parallelism as described above, until it coincides with the moon; to proceed further, would be to reflect the moon to the sun, which can seldom be done. But an easy and obvious expedient prevents the necessity of this; for, by turning the instrument with the divided side downwards, we place it in a position which changes an observation to the right into one to the left; and, consequently, in this position, the sun may again be reflected to the moon; thus, by alternate motions of the indices B and A, in alternately reversed positions, we gain a set of repeated observations, always reflecting the image of the brighter object to the fainter. *

Upon the index A, and half-way between the centre and horizon-glass, is a socket for holding a dark glass, which being screwed there, modifies the rays of a bright object, after being reflected from the index-glass; but is out of the way of those rays, when they pass again reflected from the horizon-glass to the eye. Close behind the horizon glass, is a similar socket for the same purpose; a dark glass applied here, will soften the direct rays, in cases where both objects are too bright for the eye, and in the few cases where the fainter image may be reflected. But as dark glasses, in either position, would intercept the incident rays, in very small angles, we find another application of darkening glasses for the reflected rays, the position of which is immediately before the index-glass, which they completely cover; these are not half so dark as those first described, because the rays of light pass twice through them, once before reflection, and again afterwards; three or more glasses of different colours and shades are applied at each of the three positions, but only one at a time can be used at any of them.

---

* Analogous to this, it should have been stated, in the method of observing with Mayer's circle, that when the brighter object is to the right, the face of the circle must be used upwards; but when it is on the left, the face must be used downwards.

Whatever we have yet said respecting Borda's principal improvement, it must have its value appreciated fully as much for economy of time as accuracy of result. But when we consider that circles like Mayer's, as well as octants and sextants, have the angles which are measured by them charged with the full amount of the errors in the darkening glasses, Borda's construction must rise greatly in our estimation, and set its competitors at a distance. His method of making crossed observations completely destroys these errors; for, affecting the contacts to the right and left, by equal quantities, in contrary directions, they will, in every pair, correctly balance each other.

Plate CXLIV. Fig. 2.

The telescope of Borda's circle is attached to the index A by two cocks; these have each a slider, by which its line of collimation may be set parallel to the plane of the circle, as well as raised or depressed for the purpose of darkening or brightening the reflected image, by placing less or more of its aperture opposite the silvered part of the horizon-glass. Both the indices A and B are furnished with apparatus for quick and slow motion. A handle is screwed to the back of the circle at the centre, and stands perpendicular to its plane. This instrument has usually been made of 10 inches diameter, and divided to every minute; the whole limb comprehending, like all reflecting instruments, 720°. This is owing to the well-known law in catoptrics, that the angle of reflection is, in all cases, equal to the angle of incidence, and not on account of double reflection, as some authors have erroneously stated.

Sect. III. *Description of Troughton's Reflecting Circle.*

Description of Troughton's reflecting circle.

Many of the circles of Borda had been made in London by several different artists, chiefly for foreign orders, and for the late Mr J. H. de Magellan, who made a few trifling alterations in its construction, and who put in an ineffectual claim to the invention of the method of making crossed observations. It was in 1794 that one of those artists, Troughton, imposed upon himself the task of bringing forward, in an improved form, an instrument which hitherto seemed to have drawn towards it the attention of foreigners alone. We have heard Mr Troughton say, that it was with the utmost hesitation he dispensed with the repeating principle in his new construction; but considering that a well divided instrument can derive little or no advantage from its employment, and seeing that its rejection would afford him the means of a simpler and firmer fabric, he determined to put into the hands of his customers an instrument which, though greatly superior in precision, was in use and management not much different from those they had been accustomed to handle.

Plate CXLIV. Fig. 3. Fig. 4. Plate CXLV.

Plate CXLIV. Fig 3. is a representation of this instrument, exhibiting the face or side on which the divisions are made; and Fig. 4. as well as the perspective view, (Plate CXLV.) shews the construction on the reverse side, or side of the glasses. The simple border, with bars radiating from the centre, answers sufficiently well in Borda's instrument, where the weight is sustained on the handle at the centre; but, in the case now before us, where there are two handles applied parallel to the plane of the circle, and one of them bent round from the side to which it is fixed, a different figure was required. After many forms had been tried, that which is here given was alone found to preserve its shape unvaried in all positions. The handles are attached to the frame by screws at two opposite parts, where the bars cross each other; but besides this, they are also stayed at the centre. The index has three branches, at equal distances from each other; one of them carries the usual apparatus for quick and slow motion, which being set fast, or put in gradual action, governs also the other two. To this index is fastened an axis, which, after passing through a socket about two inches long, carries at the other end the index-glass. A secondary frame, attached to the main one by five pillars, is situated nearly an inch below it; upon this secondary frame are firmly fixed the horizon-glass and the telescope; on the same frame are also placed two sets of coloured glasses, one between the index and horizon-glasses, and the other behind the latter of them; the first for darkening the reflected image of a bright body, the second for darkening one seen directly. The distance between the two frames affords a relief, whereby the coloured glasses may be turned down, round a joint, for placing them out of the way when they are not wanted. The telescope with different powers screws into a collar, whose squared stem having its four angles worked through its whole length into a screw, passes through a barrel, which connects the main and secondary frames: the bore of the barrel is square next the telescope, and receives the squared stem of the collar; but higher, it is cylindrical and large. In this part, a spiral spring is enclosed, which exerting its force against the enlarged higher end of the stem, draws it along with the telescope upwards, while, at the exterior end of the barrel below, a female finger screw, acting on the stem, draws it downwards, and both together affords, by one action, the means of adjusting the telescope respecting the line of separation between the silvered and unsilvered parts of the horizon-glass; by this contrivance, the two objects under observation may be made of equal brightness, without taking the eye off them. There is also in the collar into which the telescope screws, the usual adjustment for making the line of collimation parallel to the plane of the circle.

It has already been said, that Bird's construction of Mayer's circle is, in this respect, preferable to Borda's; the latter is indeed very inconvenient, because with it an observer has to read the divisions of the two sliders, by which the height of the telescope, from the plane of the circle, is regulated; for should he, while observing, attempt any alteration, by using the two screws to suit the objects as their brightness varies, and happens to turn one of them more than the other, he would derange the parallel position of the telescope, and thereby render his observations of no value. The circle of Borda is, in many respects, mechanically defective; that highly important part, the centering of the indices, is very much so, for they move round the circle upon bearings no longer than their own thickness; and, consequently, want that steadiness which is derived from an axis.

The author of the reflecting circle now under consideration, had many reasons for furnishing its only index with three verniers. In the first place, he was desirous that as the repeating principle had been abandoned, some contrivance should be substituted for the purpose of reducing the errors of even good dividing. Three readings which, upon the principle of taking means, in a crossed observation, (a term we need no longer employ), probably reduce the error of dividing to one sixth part of its simple value; while, at the same time, they perfectly correct the error arising from any eccentric motion of the index. This kind of error, a very important one, is never entirely corrected in Borda's circle, except in the case of beginning and leaving off at the same point; for, should the repetitions be continued to more than a complete round, the error which at that point must have vanished, would be again generated.

Moreover, the three readings, when the angle measured is the sextantal one (120°) in a backward and forward observation, (answering to right and left in the other constructions), will just occupy the 720° degrees of this circle.

It might have been sooner noticed, that the degrees of this circle are subdivided into three parts of 20′ each, and that each branch of the index subdivides to 20″, the verniers having 60 divisions, whose length is equal in extent to 59 of those upon the limb.

The dark glasses, in sets of three, are fixed to the instrument in such a manner, that any or all of them may be used at the same time, as circumstances may require. This gives the circle before us a decided superiority over all the others. Nor is it a matter of small importance, with respect to convenience, that a handle is found both above and below: By one or other of these, in every possible position of the instrument that observations can require, it may be held right or left, as is found most convenient to the observer. It must, however, be acknowledged, that the reflecting circle is, under the best circumstances, held two or three inches farther from the observer than the sextant is, and, of course, bears proportionally heavier upon his arm. Mr Troughton is of opinion, that this inconvenience is the principal if not the sole cause, that the circle has not yet come into general use; but we would hope, that an inconvenience so trifling, cannot deter a good officer from exercising the best means of obtaining the truth; especially, when we consider how much is entrusted to his care, and that the safety of the whole depends, in a great degree, upon ascertaining, in a long voyage, a few points of longitude and latitude, upon which, with confidence, he can rely.

We are given to understand, that our present astronomer royal is a warm friend to the circle; and that, in the preface to the next publication of Nautical Almanacks, he intends to recommend this instrument. From the regard we have for the improvement of nautical science, we sincerely wish that Mr Pond's endeavours to extend the use of the reflecting circle may be as successful as he can desire.

The following instructions for adjusting and observing with Troughton's reflecting circle, may be acceptable to many of our readers. They are copied from a printed paper, which is usually given with the instrument.

Directions for Observing with Troughton's Reflecting Circle.

Directions for using Troughton's reflecting circle.

"Prepare the instrument for observation by screwing the telescope into its place, adjusting the drawer to focus, and the wires parallel to the plane, exactly as you do with a sextant: also set the index forwards to the rough distance of the sun and moon, or moon and star; and, holding the circle by the short handle, direct the telescope to the fainter object, and make the contact in the usual way. Now read off the degree, minute, and second, by that branch of the index to which the tangent-screw is attached; also, the minute and second shewn by the other two branches; these give the distance taken on three different sextants; but as yet, it is only to be considered as half an observation: what remains to be done, is to complete the whole circle, by measuring that angle on the other three sextants. Therefore set the index backwards nearly to the same distance, and reverse the plane of the instrument, by holding it by the opposite handle, and make the contact as above, and read off as before what is shewn on the three several branches of the index. The mean of all six is the true apparent distance, corresponding to the mean of the two times at which the observations were made.

When the objects are seen very distinctly, so that no doubt whatever remains about the contact in both sights being perfect, the above may safely be relied on as a complete set; but if, from the haziness of the air, too much motion, or any other cause, the observations have been rendered doubtful, it will be advisable to make more: and if, at such times, so many readings should be deemed troublesome, six observations, and six readings, may be conducted in the manner following. Take three successive sights forwards, exactly as is done with a sextant; only take care to read them off on different branches of the index: also make three observations backwards, using the same caution; a mean of these will be the distance required. When the number of sights taken forwards and backwards are unequal, a mean between the means of those taken backwards, and those taken forwards, will be the true angle.

It need hardly be mentioned, that the shades, or dark-glasses, apply, like those of a sextant, for making the objects nearly of the same brightness; but it must be insisted on, that the telescope should, on every occasion, be raised or lowered, by its proper screw, for making them perfectly so.

The foregoing instructions for taking distances, apply equally for taking altitudes by the sea or artificial horizon, they being no more than distances taken in a vertical plane. Meridian altitudes cannot, however, be taken both backwards and forwards the same day, because there is not time: all therefore that can be done is, to observe the altitude one way, and use the index-error; but even here, you have a mean of that altitude, and this error, taken on three different sextants. Both at sea and land, where the observer is stationary, the meridian altitude should be observed forwards one day, and backwards the next, and so on alternately from day to day; the mean of latitudes, deduced severally from such observations, will be the true latitude; but in these, there should be no application of index-error, for that being constant, the result would in some measure be vitiated thereby.

When both the reflected and direct images require to be darkened, as is the case when the sun's diameter is measured, and when his altitude is taken with an artificial horizon, the attached dark-glasses ought not to be used: instead of them, those which apply to the eye-end of the telescope will answer much better; the former having their errors magnified by the power of the telescope, will, in proportion to this power, and those errors, be less distinct than the latter.

In taking distances, when the position does not vary from the vertical above thirty or forty degrees, the handles which are attached to the circle are generally most conveniently used; but in those which incline more to the horizontal, that handle which screws into a cock on one side, and into the crooked handle on the other, will be found more applicable.

When the crooked handle happens to be in the way of reading one of the branches of the index, it must be removed, for the time, by taking out the finger-screw, which fastens it to the body of the circle.

If it should happen that two of the readings agree with each other very well, and the third differs from them, the discordant one must not on any account be omitted, but a fair mean must always be taken.

It should be stated, that when the angle is about thirty degrees, neither a distance of the sun and moon, nor an altitude of the sun with the sea horizon, can be taken backwards; because the dark-glasses at that angle prevent the reflected rays of light from falling on the index-glass; whence it becomes necessary, when the angle to be taken is quite unknown, to observe forwards first, where the whole range is without interruption; whereas, in that backwards, you will lose sight of the reflected image about that angle. But in such distances where the sun is out of the question, and when his altitude is taken with an artificial horizon, (the shade being applied to the end of the telescope,) that angle may be measured nearly as well as any other; for the rays incident on the index-glass will pass through the transparent half of the horizon-glass, without much diminution of their brightness.

The advantages of this instrument, when compared with the sextant, are chiefly these: The observations for finding the index-error are rendered useless, all knowledge of that being put out of the question, by observing both forwards and backwards. By the same means the errors of the dark-glasses are also corrected; for, if they increase the angle one way, they must diminish it the other way by the same quantity. This also perfectly corrects the errors of the horizon-glass, and those of the index-glass very nearly. But what is still of more consequence, the error of the centre is perfectly corrected, by reading the three branches of the index; while this property, combined with that of observing both ways, probably reduces the errors of dividing to one-sixth part of their simple value. Moreover, angles may be measured as far as one hundred and fifty degrees, consequently the sun's double altitude may be observed when his distance from the zenith is not less than fifteen degrees; at which altitude, the head of the observer begins to intercept the rays of light incident on the artificial horizon; and, of course, if a greater angle could be measured, it would be of no use in this respect.

This instrument, in common with the sextant, requires three adjustments. First, the index-glass perpendicular to the plane of the circle. This being done by the maker, and not liable to alter, has no direct means applied to the purpose: it is known to be right, when, by looking into the index-glass, you see that part of the limb which is next you reflected in contact with the opposite side of the limb, as one continued arc of a circle: on the contrary, when the arc appears broken, where the reflected and direct parts of the limb meet, it is a proof that it wants to be rectified. The second is, to make the horizon glass perpendicular. This is performed by a capstan-screw, at the lower end of the frame of that glass; and is known to be right, when, by a sweep with the index, the reflected image of any object will pass exactly over, or cover the image of that object seen directly. The third adjustment is, for making the line of collimation parallel to the plane of the circle. This is performed by two small screws, which also fasten the collar into which the telescope screws, to the upright stem on which it is mounted: this is known to be right, when the sun and moon, having a distance of one hundred and thirty degrees, or more, their limbs are brought in contact, just at the outside of that wire which is next to the circle; and then, examining if it be the same, just at the outside of the other wire: its being so is the proof of adjustment."

Description of the stand for the reflecting circle.

PLATE CXLV.

Plate CXLV. was chiefly designed to represent the stand, whereon the British construction of the reflecting circle has been frequently mounted for making observations on shore, such as, by the aid of an artificial horizon, we obtain altitudes of the heavenly bodies for the latitude or time, as well as by the lunar observations, to find the longitude on land. This perspective view was also intended to exhibit such parts of the instrument as are not sufficiently shewn in the other Figures.

At the bottom of the Plate, we see the tripod of the stand is supported by three finger screws, the use of which is not for placing the instrument perpendicular, which is their usual office; they are here designed to bring the objects under observation, exactly into the centre of the field of view, after having been brought nearly thither by hand. They also give that small motion which is required to make the images pass each other, for ascertaining the points of objects which ought to be brought into contact. These screws thus produce, in the simplest and neatest manner, the full effect that could be gained, were all the motions of the stand governed by adjusting screws. A vertical pillar is inserted into the centre of the tripod, and unscrews there for the sake of snug-packing. At the top of the pillar, and within it, there is an axis whereon the instrument turns round horizontally: this motion respecting stiffness being regulated by a finger screw at top. A cross piece above the pillar, to which it is attached, bears at its ends, about four inches apart, two upright supporters, in which is centered an axis at right angles to the former. The motion round this axis may also be clamped or set free, by two finger screws at its opposite ends. By these two motions, the circle may be placed in any position that observations can require. Two counterpoising cylinders, whose connecting levers apply at the ends of the horizontal axis, keep the instrument at rest in all positions. There is a socket fixed at right angles to the middle of the horizontal axis, through which the shank of a screw passes; and there is a cock firmly fastened to the centre of the circle, which receives the *tapped* end of the screw, just clear of the index-glass, binding the circle and stand strongly together, yet allowing a free motion of the former in its own plane round the shank of the screw as an axis.

The three motions of the stand above described are all essential; for with fewer the varied compound motion of the hand cannot be imitated. Steadiness in a stand for a reflecting instrument would be a property of no great value; for its only use is to relieve the arm of the observer from the weight, and allow him the free use of both his hands; one of which is always wanted to act upon the index-screw, while the other is required at the screws of the tripod; and, at the very moment of contact, should perhaps always be employed at the eye-end of the telescope, touching also the face of the observer, and thereby preventing the wandering of the eye. Thus mounted, the reflecting circle becomes of itself a little observatory, and enables a skilful observer to turn it to good account in the sciences of astronomy, geography, and navigation.

The greatest error to which dividing by a good engine is liable, we think may be taken at about 20″; the six readings required in a double observation, on different parts of the circumference, will probably reduce that error to within 5″; where the reflecting glasses and telescopes are good, and power considerable (about 12), a mean of contacts will come out within this quantity. And where every other source of error is corrected by the principles of the instrument, we are of opinion that a series of lunar observations will give the longitude on land nearly, if not quite as accurately, as can be obtained from an occultation of a star by the moon, when observed with a powerful telescope.

When the Lunar Tables, &c. of Mayer, as improved by Mason, were used for the construction of the Nautical Almanack, the sextant, as it came from the hands of our best makers, was, in point of exactness, nearly on a level with its columns: but the Tables of Gauss, computed from the theorems of La Place, left both far behind. These now, however, form the basis of our Almanack, and an instrument of commensurate exactness is to be found in the British circle.

With the reflecting circle so constructed, the Almanack so improved, and with Captain Mendoza's excellent Tables, which far surpass every thing of the kind seen before, finding the longitude, either at sea or land, is no longer either a doubtful or a difficult operation.

We shall close our observations on the reflecting circle with some account of the laudable endeavours of the gentleman, whose name has just been mentioned, to improve it, and to render it a companion worthy of his other nautical labours.

Sect. IV. *Description of Mendoza's Reflecting Circle.*

Mendoza's reflecting circle.

In a paper published in the *Phil. Trans.* for 1800, Captain Mendoza has described, at considerable length, one construction, and briefly mentioned others, all of which, however, lead only to extend the repeating principle. We shall confine our account to that which, to ourselves, appears to be the best, and we refer to the paper itself for farther information. It is offered as an apology for not having given a figure of this circle, that it is easy to describe its peculiarities in words, but extremely difficult to make them appear in a drawing.

The general fabric of this circle is, respecting the frame, position of the glasses, and handles, exactly as in Troughton's construction, to which the repeating property has been restored in a very ingenious manner, and so as to produce double the effect that is done in Borda's, by collecting the sum of backward and forward motion of the index into one reading. For this purpose, there have been added two very light circles, one of which he calls a flying circle, and the other a flying nonius. They are both centred upon the upper end of the socket, which receives the axis of the proper index, and of the great mirror. The motions of these two circles are free and independent of each other: they are situated one above the other close to the limb of the fixed frame, having no connection whatever with it, except at the centre. It will be remembered, that, in the former construction, the index with three branches had backward and forward motion; it is precisely so in this, only this index has but one branch, namely that with the screws for quick and slow motion. This index carries no vernier, nor are there any divisions upon the limb of the fixed frame to which it applies. The graduation is made upon the flying circles, the lower of which is divided into degrees, and every 20′; the upper one carries opposite verniers, subdividing the lower down to 20″. There is a clamp attached to the index, which lays hold of the flying nonius, and in an observation forwards carries it along over the face of the flying circle; and there is a similar clamp, which, laying hold of the flying circle in an observation backwards, carries it back under the flying nonius. The flying circle is, in the former case, clamped to the limb of the fixed frame, and in the latter, the nonius is secured in the same manner.

Now, as in the observation forwards, the nonius advances upon the circle, and in the one backwards, the circle recedes upon the nonius, it is evident, that the sum of the two motions will be given at one reading off. Instead, however, of reading here, forward and backward observations are to be repeated, until a sufficient set has been procured, and then the whole space that the circle and nonius have been moved respecting each other may be read off, and on being divided by twice the number of forward and backward motions together, will give the required angle. There are two sextants of coarse divisions made upon the fixed limb, whose *zeros* are distant from each other by the breadth of the index of the index glass; contiguous to these divisions slide two pieces, which, being set right and left to the angle about to be measured, will stop that index in the requisite positions for finding the objects nearly together in the field of the telescope. This useful contrivance enables an observer to take a set of sights of any number without looking at the divisions, the first and last excepted.

Mr Troughton first applied this neat contrivance to the circle of Borda, which, without it, is extremely inconvenient to use. It ought to have been mentioned in the account of that instrument, that a previous rough observation must be made for computing at what points upon the limb the two indices must be set, in order that the objects may be found together in the field of view; and it requires the observer, at every successive sight, to set the indices alternately to the computed angle; but, with this apparatus, a set may be taken in the dark.

Notwithstanding the great ingenuity displayed in these contrivances, we think that the reflecting circle last described, can neither be very accurate nor very pleasant in its use: the management of five clamps, which are to be made fast and loose in regular succession ten distinct operations to every pair of observations, any of which being mistaken or neglected would spoil a whole set, requires a degree of attention not to be found in every observer. And the liability which there must be, even in the best work, to force the flying circles from their places in clamping, and thereby to cause errors, without any means of detecting them, is a most forbidding circumstance. And should the index of the central mirror have a motion eccentric to those of the flying circles, the latter at every step will feel the effect, and in consequence, the result will be charged with the full error belonging to a single observation.

Sect. V. *Professor Hassler's Method of restoring the Reflecting property to Troughton's Circle.*

Professor Hassler's method of restoring the reflecting property to Troughton's circles.

Since the above was written, we understand that there has been suggested to Troughton an unexceptionable method of restoring the repeating property to his reflecting circles, without in the least diminishing the advantages of the fixed frame. In this the circular border of the frame is not employed; it has one flying circle, (which was probably borrowed from the instrument last described,) and it is divided in the usual manner. Two indices are employed; one of them, below the circle, is screwed fast to the frame, the other is above, having, like the circle itself, free and independent motion round the centre; the latter carries at the lower end of the axis the index-glass. Both of the indices have screws for quick and slow motion, which act upon the flying circle; and they are both furnished with opposite verniers, those of the lower index being brought round from below, in order to count upon the divisions of the circle. When the index and horizon glasses are parallel, the two indices cross each other at right angles; therefore the upper one has a range of backward and forward motion through the full sextantal angle, without interfering with the lower one.

The effect produced by this arrangement is as follows. In an observation forwards, the circle being clamped by, the fixed index, the moveable index advances upon the circle, and being clamped to it, the contact of objects is made by its proper screw. And in an observation backwards, the circle being released from the fixed index, is carried backwards along with the moveable one, receding upon the former, to which it is again clamped, and then the contact of objects is made as before. These alternate operations must be continued until a set is obtained; and then the upper index will give the amount of forward, and the lower that of backward observations. With respect to repeating the angle, this instrument produces the same effect as Borda's circle; but we cannot here come at the double result, as we did in the arrangement of Mendoza. In this latter, however, the clamping is performed after the contacts are observed, which is its great defect; but the former has no such impediment, the clamps being fixed before the contacts are made; and therefore, in this respect, stands equal to a sextant, or any of the former constructions of the circle.

To such gentlemen as wish for a reflecting circle which repeats the angle, we hesitate not to recommend the one we have just endeavoured to describe; and we have to inform the public, that they are indebted for the idea to Professor Hassler, a native of Swisserland, and a distinguished citizen of the United States of America.

CHAP. II.

Description and Use of the Portable Altitude and Azimuth Circle.

SECT. I. *Description of the Altitude and Azimuth Circle.*

Portable altitude and azimuth circle.

IN our article ASTRONOMY, we gave to our readers the figure of an altitude and azimuth circle, with a short description; and we there stated, that the instrument itself had been recently made for the observatory of Colonel, now General, Brisbane. That instrument was constructed upon the model of the one used at Westbury, by our present astronomer-royal; and the observations which he there made with it, enabled him to give to the public that admirable catalogue of some of the fixed stars, which appeared in the *Philosophical Transactions* for 1806. But as that instrument was of too large dimensions for convenient carriage, as the azimuth axis was long and pointed downwards, greatly enlarging the bulk of package, and as it required a pedestal of peculiar structure; however desirable these properties may be in an observatory, for which it was solely formed, it was rendered thereby quite unportable, and altogether inapplicable to geodetic purposes.

Plate CXLVI.

We have now before us, (Plate CXLVI.) the figure of an instrument, which is free from the inconveniences above stated, the external appearance of which, we presume, will engage the attention of our readers in its favour. In confidence that this will be the case, we shall, without further encomium, proceed to describe its construction and adjustment. We may, however, first premise, that in astronomy it is equally well adapted to the various purposes of the transit, quadrant, and equal altitude instrument; and in the field, it is capable of performing the office of the most improved theodolite, and levelling instrument.

The figure bears the date of 1810, the year in which the circle it was drawn from was really made; but 1792 is the date of its first production by the artist, whose name it bears.

Beginning our description at the bottom, the part BB represents a strong tripod, the feet-screws of which, A, A, with milled heads downwards, support the whole, and enable it to stand upon a table, window-seat, or stone pillar, as circumstances may require; its own packing-box is also fitted up for a pedestal, and serves in cases where a better cannot be provided. Immediately above the tripod, and in close contact with it, is the azimuth circle CC; centered upon a vertical axis, which is strongly united with the tripod at its centre. This circle is connected with the tripod, not only by the axis round which it turns, but also at three places near its border, but in such a way as to admit of a motion of three or four degrees only, wholly governed by a slow-moving screw, the head of which is seen below to the right. Below, and on the left, appears the eye-end of a telescope R, which is furnished with the means of vertical and horizontal motion. It is fixed to the circle, (not the tripod,) and partakes of the same motion with it, when acted on by the slow-moving screw. Round the vertical axis already mentioned, on the conical socket D, revolves the azimuth index, near to the circle, but yet without touching it. This index is, like the circle, an entire plate, deep for the sake of strength, and hollow for the sake of lightness; the edge terminates in a half contrate border, as appears at E. The index may be clamped fast to the circle by a screw, the head of which is shewn at *a*, when another, represented at *b* furnishes a gradual slow motion. Two micrometer-microscopes FF, for subdividing and reading the divisions of the circle, are well secured to the index by three pillars each. Their positions are on directly opposite points of the index with which they revolve.

At right angles with the microscopes, are erected upon the index two stout pillars GG, the use of which is chiefly to sustain the weight of the upper part of the instrument, and to render steady the ends of the transit axis. These pillars are connected by a piece T, with the socket of the azimuth axis near its upper end, by which means the pillars and socket are made mutually to support each other.

The principal part of the weight of the upper works is made to bear upon the tops of the pillars, and is sustained by a friction-wheel at the centre of each, as at *g*. These wheels are urged upwards by a spiral spring, the force of which is nearly equivalent to the incumbent pressure. On receiving the weight, the wheels retire within the pillar, and allow the different parts to find their proper bearings.

For the purpose of supporting a horizontal axis 16 inches long, which is nearly twice the distance of the pillars, a strong piece, as at *e*, projects outwards horizontally from each, and to these are affixed the adjustable angles, in which the ends of the axis rest, as shewn at *d*. The horizontal axis H, thus supported, forms the central part of the altitude circle IIII. This circle is double, each part being well connected with the axis, and as firmly united to the other, by short pillars placed perpendicularly between them. The divisions of this circle, as the one below, are degrees subdivided to every five minutes, and like them are read by micrometer-microscopes, which again subdivide to every single second. The microscopes are attached to the extremities of two bent conical tubes NN, which are screwed fast to one of the great pillars: the microscopic part is denoted by SS, and the scales, which exhibit the subdivisions, are represented at *h*, *h*. The circle is acted on by a quick and slow moving apparatus K, which is made fast to the opposite pillar, as shewn at G. It is so formed as to oppose a stout resistance in the direction of the plane of the circle, but in the line of the axis it is extremely flexible. The telescope ZZ passes through the central part of the horizontal axis, to which it is fastened; it is also united to the double circle, between the parts of which it is situated. A lantern, not represented in the Figure, applies to one of the large pillars, opposite to the end of the axis, on the reverse side, from which light is directed through the axis, perforated for that purpose, and falling upon a plane covered with gold-leaf, is from thence reflected to the eye, for the purpose of illuminating the field of view of the telescope. A level, as shewn at X, hangs upon two pivots fixed to the crooked supports of the microscopes, and occupies a position between the pillar and divided side of the circle: one of its pivots is adjustable by the finger-screw *r*. The level has sliding ivory scales, which indicate to a second the position of the parts with which it is connected. A similar level, not represented in the Figure, applies occasionally to the pivots of the horizontal axis, upon which it is made to rest when in use, having been previously passed through between two of the radii of the double-framed circle. This has also sliding divided scales, and, like the other, indicates single seconds.

The instrument above described is of moderate dimensions, the diameter of the vertical circle being 18 inches, and that of the horizontal one 15 inches. They are both divided by lines (not dots) into spaces of five minutes, and the parts actually divided are, by their respective micrometers, subdivided and read, as was said above, to every second. The essential part of those micrometers consists of two wires, which cross each other like an X, and are moved along by a fine screw, in the direction of a tangent, to that part of the circle which may be opposed to them. When the cross is at the *zero* of its scale, it is the index of the divisions of the circle, and the quantity to be measured by the motion of the cross is that by which the next dividing line has passed beyond that *zero*, and is always additive. The general construction of this micrometer is not materially different from the parallel-line one, which was described in our article ASTRONOMY.

The length of the upper telescope is 30 inches, the aperture of its object-glass 2 inches, and its magnifying power about 60. It is indeed furnished with eye-pieces of both less and greater power than this, which may have their use in particular cases; but in general, this is reckoned the most useful power for such a telescope. The lower telescope is only about 18 inches in length, and its aperture and power proportionable. The whole height of the instrument is something more than three feet, and its weight is about 75 pounds.

In the eye-piece of the upper telescope are placed five vertical and five horizontal lines, the angular distance of which is about 6′ 24″ of a degree; this distance, when the sun's diameter is 32 minutes, allows an equal portion of time between all the ten contacts in observing his transit, or passage over the meridian. The five horizontal lines are for the purpose of observing equal altitudes, and when the diameter of that luminary is as above, will, without moving the circle, afford ten distinct sights, and these also will be equal to each other.

The lower telescope has in its focus only two cross wires. It is never elevated to the heavens; its only purpose being to *keep watch*, so as to shew if the whole instrument preserves its position unvaried respecting some distant object, while a set of observations is carried on.

In the eye-end of the upper telescope there are several adjustments. One of these is for placing the cross-lines in the focal point of the object-glass; and this is effected by drawing out or pushing in the whole of the eye-piece respecting the main tube. The whole eye-piece also admits of a limited motion round the axis of vision, whereby the cross-lines are adjusted respecting their vertical and horizontal position. The plate in which the cross-lines are inserted, is acted on horizontally by two opposite screws; they draw, and produce that adjustment, which places the intersection of the middle lines perpendicular to the horizontal axis. When this is verified by reversing the circle upon its angular supports, the line of collimation of the telescope will describe a great circle round the axis on which it revolves.

The cross-lines of the lower telescope are also acted on by two screws, like the upper one; but these are for no other purpose than for bisecting an object with the greatest accuracy, which cannot be done by the motions of the telescope itself, because they are not governed by adjusting screws.

To proceed in our account of the adjustments of this instrument, we find the feet-screws ready for placing the vertical axis truly perpendicular. This they will do by help of the level X, which having its bubble brought to the divided scales in any position, and then the instrument being turned half round in azimuth, an error will appear the double of that by which the axis is inclined; one half therefore must be corrected by the feet-screws, and the other by the screw *r* which acts upon the level. This will set the axis perpendicular in the direction of the level; and now, the instrument being turned through a quadrant, and the level brought by the feet-screw again to the sliders, this adjustment will be effected. The first part of the operation is best performed with the level in the direction of two of the feet-screws, because the second may then be made by the other screw without danger of deranging the first. It need scarcely be mentioned, that the operation should be repeated for greater exactness; nor that, when the adjustment is perfect, the bubble of the level will preserve its centrical position, while the instrument is turned quite round in azimuth. By this adjustment, the telescope is made to describe lines parallel to the horizon. The reading microscopes may now be adjusted to their places, so as to have their *zeros* exactly in the diameter of the azimuth circle.

The next great adjustment is to place the vertical circle at such a height, that its two microscopes shall be directed to two opposite points in its horizontal diameter. This is done by the screw *f*, which, acting upon the angular bearings of the horizontal axis, carries it up or down, as may be required. The farther pillar has the same kind of screw, which acts in like manner upon the support of the opposite end of the axis. It must here be mentioned, that through an inadvertence of the maker, the draftsman had access to the instrument, at a time when the angular bearings *d* were screwed almost out of their sockets *e*, on which account the socket and friction-wheel *g* appears to lift the circle too high; and the draftsman, knowing that the microscopes should occupy the line of the horizontal diameter of the circle, added that part in the tubular support which is seen between the circular rings, which part was not to be found in the instrument.

With the microscopes now in the diameter of the circle, and the vertical axis perpendicular, place the detached level upon the axis, in such a manner that it may touch nothing else; now if it does not settle with the ends of the bubble at the divided scales, move the scales to the bubble, if it is within their range; but if it is not, bring the bubble to the scales, when placed at equal distances from the middle, by means of the screw *f*, and its fellow on the opposite pillar. Then reversing the ends of the level, see if the bubble settles at the indices; if it does not, alter one half of the apparent error by *f* and its fellow, and the other half by the sliders of the level. The instrument will now give azimuths and right-ascensions, (that is, when placed correctly respecting the meridian,) but without farther adjustment, zenith-distances are only indirectly to be obtained from it.

To adjust it in this respect, we may proceed as follows: Point the telescope to any very distant object, which bisect by the middle horizontal wire, and read off by the microscopes the apparent zenith distance; now reverse the instrument in azimuth, and turning the telescope again upon the same object, bisect it as before, and again read off the angle which they shew. One of these will be an altitude, and the other a zenith distance. On one being reduced to the same name as the other, the mean of them will be the true zenith distance or altitude respectively; and while the telescope bisects the object, the microscopes must be adjusted by their proper screws, so as to shew that mean. This operation may be repeated for obtaining a greater degree of accuracy; but its final determination should be deduced from observations upon many heavenly bodies, and the minute error that may remain unadjusted had better be allowed for.

The above are the grand adjustments of the circle before us; but there are many others which, to describe minutely, would require separate drawings. We do not, however, see the necessity for this; for the general reader will, by what has already been said, come at all he can want—a general knowledge of its construction, properties, and use; while those persons, who possess such an instrument, will, besides the above, have their attention guided to the parts of action; and the ingenious artist, who may attempt the making such instruments, will, by our description and figure, be enabled to proceed; for his own resources ought to supply what may be but partially represented. A brief enumeration, however, of some of the minor adjustments are here subjoined.

The microscopes of both circles have an adjustment for placing them in the exact diameters of their respective circles, which adjustment also sets them at their proper distance from the centres. By another adjustment, the whole length of the microscopic tube is varied, in order to make the magnified image of a division exactly measure the scale of five revolutions of the micrometer screw. A consequent adjustment of backward or forward motion of the whole tube restores distinct vision, which was necessarily lost by the former operation. The five single minutes are indicated by as many notches, seen at the side of the field of view of the microscopes; they are indented by the micrometer screw itself, and are adjusted to their place by a screw at the end of the box, opposite to the micrometer head, acting upon the plate which contains them. By these means, a revolution of the screw becomes the exact measure of a minute; and it only requires the head of that screw to be divided into 60 equal parts, in order to give seconds. This circular scale of seconds has a motion round the head, whereby its *zero* may be brought to the pointer, without moving the cross lines within.

Both the levels are constructed without adjusting screws, the moveable divided indices answering the same purpose; for if the point of adjustment, as ascertained by reversion, be within the range of the bubble, the performance will be equally accurate, as it would have been, had that point been in the middle of the tube.

It may be remarked, that, after the principal adjustments have been carefully made, they should not be disturbed on slight occasions. If, therefore, the horizontal axis were occasionally found to be out of level, to the amount of a second or two, it would be wrong to adjust it by the screw *f* or its fellow, because that would affect the circle respecting its reading microscopes. Such a small deviation would be best corrected by touching one or more of the feet screws.

Of the instrument which we are now about to dismiss, it has been said, that its principal telescope magnifies 60 times, and that the angles are read to single seconds; and we may add, that the circles being divided by an accurate engine, the work of which is estimated to be within 5″ of the truth, and the levels, by which the verifications are made, being ground to a long scale, so as to be depended on to less than 2″, reasonable expectations may be formed, that when used under favourable circumstances, two observations, in reverse positions with it, will give the place of an object in the heavens, in declination within 5″, and in right ascension within 0.5″ of time. Nor can much of this degree of accuracy be abated, where, in surveying, land objects are observed; but much depends here upon what kind of objects present themselves for bisection.

Small as the errors of this instrument, as just stated, may appear, contrivances have been suggested and applied, which reduce them to almost nothing. To give the horizontal circle this advantage, the top of the pedestal should be made double, and the upper half moveable in azimuth, carrying the instrument round with it, but capable of being firmly secured in any given position. By this contrivance, an angle in azimuth may be measured on as many different parts of the circle as may be thought necessary. This, in truth, gives to this instrument a property, but little inferior to the far-famed method of repetition.

A contrivance, which furnishes the upper circle with a similar advantage, was suggested by the ingenuity of our present astronomer-royal, as stated in his paper upon the declination of some of the fixed stars, (*Philos. Trans.* for 1806.) This is effected, by giving the reading microscopes a motion of about 60° concentric with the circle: for the sun and moon, which are continually changing their meridian altitudes, no such contrivance is necessary, except indeed for the former, at the points of his greatest declination; but for the fixed stars, which, without it, would always have their places given by the same division, the revolving microscopes are of the greatest value. By changing the places of these as often as we think necessary, the errors of division may be reduced to a quantity too small to deserve notice. In all cases, the angle, through which the microscopes are shifted from their horizontal position, must be applied to the observations as an error of collimation.

We may observe, that this construction of the astronomical circle seems peculiarly adapted to the convenience of a scientific gentleman when travelling. Its strong and compact figure renders it safe and commodious in carriage. All its verifications may be made in a short space of time by land objects; and its being applicable to all the purposes of astronomy and geodæsy, renders it, in our estimation, superior to the repeating circle, which is, for similar purposes, its only rival.

SECT. II. *General Method of making Observations with Astronomical Circles.*

If the instrument turn freely in azimuth, and has likewise a divided azimuth circle, this circle should first be placed in a horizontal position, a verification not always absolutely necessary, (except azimuths are to be observed) but which will generally be found convenient. It is performed, by bringing any one of the levels of the instrument into a parallel line with two of the feet screws. The bulb of the level being made to rest in a central position by the action of either of these screws, the instrument is then to be moved half round in azimuth, and if the bulb of the level has changed its place, it is to be restored to its former position, half by the action of one of the feet screws, and the remaining part by the action of the screw, which changes the position of the points of suspension of the level itself. If, upon a second trial, the level remains unchanged, then the level itself is adjusted, and the instrument is to be now brought into a position perpendicular to the first position. If the level now is no longer in its central position, the *whole* deviation is to be corrected by the foot screw; a circumstance particularly to be attended to, for the level once adjusted is always adjusted, whereas the position of the azimuth circle may be correct in one position, but erroneous in all the rest.

The axis of the vertical circle should next be made horizontal. This is known to be accomplished, when the hanging level remains stationary during a whole revolution of the vertical circle round its horizontal axis; but, in many instruments, the level is not capable of revolving with the circle, in which case it must be applied and reversed end to end, till the bulb remains in the same position at each application.

In large circles intended to be used as transit instruments, the exact verification of the horizonal axis is of great importance. If the level be very sensible, it is usually furnished with a scale. In that case, it is better to read off the deviation each way, than to attempt to bring the level to a central position. This verification is performed in the following manner: Suppose the divisions of the scale to represent seconds of space, and the central division, both of the east and west end, to be marked zero, then apply the level, and take three or more readings as follows;

	East End.	West End.
	3″.2 E.	2″.1 E.
	2 .7 E.	1 .7 E.
	2 .8 E.	1 .9 E.
Mean	2 .9 E.	1 .7 E.

Mean of the two 2″.3 E.

Now reverse the level, and take three readings. Suppose

	8″.5 W.	5″.5 W.
	8 .2 W.	6 .0 W.
	7 .3 W.	6 .5 W.
Mean	8 .0 W.	6″ W.

Mean of the two 7″.0 west.

But in the first position it was 2″.3 east.

Hence the mean of two positions is 2″.3 west. This small quantity may be corrected by the adjusting screw, particularly if furnished with a micrometer head, and a similar trial repeated.

It is in this manner that the transit instrument is levelled at the Royal Observatory, and the result is registered once a week in the transit book, and published with the annual observations.

The next adjustment, if not previously attended to by the maker, is to cause the image of a star to be formed accurately on the micrometer wire, which should be placed exactly in the focus of the object glass. This requires a very careful examination. Both a star and the micrometer should be seen at the maximum of distinctness at the same time. A double star, such as Castor, γ Arietis, or γ Virginis, should be chosen for this purpose. If, when these stars are seen distinctly double, the eye-glass requires to be drawn either in or out to improve the distinctness of the micrometer wire, it is a proof that the object glass itself requires to be drawn out a similar quantity, that the image may be thrown at its proper distance. It should be remembered, that this adjustment is precisely the same for either long or short-sighted persons, the alteration required for either is to be effected by the eye-glass only. The position of the micrometer wire should next be examined, to ascertain if it be parallel to the horizon. For this purpose, let any terrestrial object be bisected, and the instrument turned slowly in azimuth, if the same object remain bisected when at each extremity of the field of view, it is a proof that the wire is horizontal. If the circle does not move in azimuth, the vertical wire may be rendered perpendicular by a similar process. In each case, the wires are supposed to be perpendicular. Should this not happen to be the case, the horizontal wire may be examined by a star in the equator, which should remain bisected during the whole of its passage, and any error in the vertical wire will be rendered of no importance, by always observing the transit of a star. On the centre, indeed, the observation must necessarily be so made, when zenith distances and right ascensions are determined with the same instrument. What we wish to point out, is the importance of paying the greatest attention to the *horizontal* wire. If the two wires are not exactly perpendicular to each other, one must be erroneously placed, and this had better happen to the vertical than to the horizontal wire.

The line of collimation should next be made to describe a great circle of the sphere. This, when the instrument admits of it, is done by reversing the vertical circle in its Y's, and observing if the same terrestrial object be accurately bisected in each position; or the instrument may be turned half round by the azimuth circle, which is an equivalent operation. In very large instruments between stone piers this cannot often be done. The observer in that case, must be provided with two accurate meridian marks, one to the north, the other to the south, and when these are once adjusted, there will be no necessity to have recourse to this troublesome operation. We shall again have to recur to these verifications under the article TRANSIT INSTRUMENT.

SECT. II. *On the Method of conducting a series of Astronomical Observations with an Astronomical Circle.*

Almost all the instruments above described, resemble each other in this common principle, that they determine the zenith distances of the heavenly bodies by a mean of two observations, one with the face of the instrument to the east, the other towards the west.

Ramsden's and Cary's instruments generally require some previous adjustments of the microscopes, that is, each microscope is supposed to mark zero, when two points or dots, marked on the limb of the instrument, are brought into a vertical position, by means of a plumb line passing over and bisecting each of them. As these dots are as permanent as the divisions themselves, the observer need not be anxious to change frequently the position of his instrument, because the error of collimation once found will remain permanently the same, as long as the micrometer wires remain undisturbed. A long series of stars, therefore, may be observed with the face of the instrument in one position; and at a very considerable interval, if it should so happen, a corresponding series may be obtained in the contrary position, and this permanency of the error of collimation, and the increasing degree of accuracy with which it becomes known, is an advantage peculiar to these instruments.

In Troughton's circles, no previous adjustment of the microscopes is necessary; but as the result supposes that every part of the instrument remains strictly the same, they cannot be too often reversed; and we would advise the observer to change their position every 24 hours, which is no objection to an instrument moving freely in azimuth.

But in whichever of these modes the instrument be constructed, it will always possess the beautiful property of pointing out to the observer, with considerable accuracy, the maximum of its own probable error, which will be shewn by the discordance of the error of collimation, as deduced from different stars, and it may be taken as a general rule, that half the extreme difference of a great number of observations, will be nearly the maximum of error to which any one determination is liable.

In instruments of Mr Troughton's construction, great care should be taken to examine the level, or bisect the plumb line point at the moment of observation; and all those little precautions which we had occasion to recommend in our general treatise on Practical ASTRONOMY, should carefully be attended to.

When the observer, however, is not desirous of deducing every thing from his own instrument alone, he had much better avail himself of the *Greenwich Catalogue*, just published (1813) for the determination of the position of his instrument, which method we shall again have occasion to recommend in describing different methods of using the repeating circle.

The above observations relate to astronomical circles generally, and are not confined to any particular instrument; but the altitude and azimuth circle of Troughton is so universal an instrument, and so proper to be placed in the hands of students who are only commencing the study of practical astronomy, that we are induced, to extend the subject by adding the directions for its use, which have been given by Mr Wollaston in his *Fasciculus*; and this has been done in so clear and perspicuous a manner, that we shall offer no apology for transcribing the author's own words.

" Let us imagine," says he, " an observer cast upon an unknown shore, with no other astronomical instrument: having indeed a chronometer; but we will suppose that to be gone down: and having likewise a Nautical Almanack, and the necessary tables for calculation. We will consider him as knowing neither the longitude nor the latitude of the place, nor the hour of the day, within 15 or 20 degrees either way. The tracing of things thus from the beginning, will best explain what may be done by an instrument of this sort; any part of which process may be omitted, according to the data he may have on which to work.

Let him first drive a small stake into the ground, or make any other mark in the pavement or floor, whereby to ascertain the spot over which he means to place his instrument. Let him also provide some screen or shade to keep off the sun's rays when he is not in actual observation: for the levels are so sensible, that any shining of the sun unequally upon the instrument, will immediately be detected by them; and he will never satisfy himself with the adjustments. Were the levels less sensible he might not perceive the difference; but that difference would really exist, whether he could discern it or not.

Let him next set his stand over the mark, and the instrument upon it, as described already; and let him adjust it in every particular as truly as he can.

Let him also wind up his chronometer, and set that to the supposed time of day.

In the morning, two, three, or more hours before noon, let him point the telescope toward the sun, and a little above it; and, clamping the vertical circle, let him follow the sun till its upper limb just touches the first horizontal wire. Then, noting down the exact second of time, as shewn by his chronometer, when that happened, let him follow the sun again till its upper limb just arrives at the second horizontal wire. After setting that down as before, let him prepare for the third or central wire; by now clamping the instrument in azimuth likewise, and holding its adjusting screw between his finger and thumb, let him bring the preceding limb of the sun just to touch the third or central perpendicular wire, at the same instant that the upper limb just touches the third or central horizontal one. Noting that instant, and setting it down, let him now read off the azimuth marked on the azimuth circle, and set it down under the other; and then prepare for making the preceding limb to touch the fourth perpendicular wire, at the same instant that the upper limb arrives at the fourth horizonal one; setting that time down again, and reading off the azimuth again, and setting it down, let him do the same by the fifth wire each way, and record them as before.

He will now find the lower limb of the sun, and its second or following limb, ready for observing in the same way at the first, second, and third wires: making each perpendicular wire a tangent to the sun's last limb, at the instant that its lower limb just leaves the correspondent horizontal wire; and setting down the time, and after reading off the azimuth, setting that down too under the other. After these, the instrument may be released in azimuth, and the lower limb alone be observed, as it quits the fourth and fifth horizontal wires respectively.

As soon as the sun has thus passed all his wires, he should read off at both the microscopes the zenith distance and altitude at which he had clamped the vertical circle; and, if he has a barometer and thermometer, he should set down their station at the same time: for, though he probably will have no occasion to regard the precise altitude at which he made these observations, yet, if any thing should deprive him of the correspondent ones, he may wish to have it in his power to deduce his time or his azimuth from these: and the reading off the microscopes after all is over is attended with very little trouble.

These things at first will appear hurrying; and till a person becomes a little accustomed to it they certainly will be so. But after a little practice, there will be found time enough to go through the whole with ease; for the vertical circle remains clamped the whole time; and all the six azimuths lie much within the limits of their adjusting screw.

The easiest method of keeping so many observations from confusion is, to have a slate, or a sheet of paper, ready ruled into five columns, to correspond with the five wires in the telescope as they occur in succession, in which to write down the observation belonging to each wire, whether that be time or azimuth. For if any cloud or accident should deprive him of any one or more of his observations, he will then at once see afterwards which of them is missing, when he comes to compare the two sets together.

Leaving the instrument clamped for altitude, and screened entirely from the sun's rays, he must wait till it is at the same distance from noon in the evening to resume his task. For that, he must hold himself ready against the time comes; and, previous to it, he will do well to re-examine the adjustment of his instrument, to be certain that no change has happened in the stand or the central cone, so as to throw its axis out of a perpendicular. Let him then observe the same method in this second set of observations as he did in those of the forenoon; considering those wires as first, at which the sun's limbs touch first; and setting down the times of their appulse to each respective horizontal wire, and bringing the preceding or subsequent limb to the corresponding perpendicular one, and reading off the azimuths just as he did before.

When all are passed, he may release all the clamps, and replacing his shade, leave the instrument till he has reduced his observations.

Of corresponding altitudes, if he has observed them all, he will have obtained ten pair; and of azimuths six pair; which he must now select from each other.

In respect of corresponding altitudes, the practice is so common, and the method of deducing the time from them is so well known, that nothing need be said on that head. Indeed, if a person wish for instruction in that, he may find it in the late Mr Wales's *Tract on the Method of finding the Longitude at Sea by Time-keepers*; which contains new tables of equations for equal altitudes, and precepts for the use of them: a valuable treatise, which may be had at a small expence, and ought to be in the hands of every one who pays attention to these subjects.

But the idea of observing corresponding azimuths being perhaps new, or at least not very common, and seemingly peculiar to this instrument, it may call for a little explanation how to reduce them: and a very little will suffice.

They must be opposed to each other in pairs, just in the same manner as corresponding altitudes; the first in the morning to the last in the evening, and so of the rest. Then, deducting the one from the other, and applying half the difference between the two to the smallest number in each pair, it will give a number of degrees, minutes, and seconds, in which, if all the observations were perfect, the whole six pair would coincide; and, if they do not, the fair mean deduced from among them will approach nearly to the truth, *i. e.* the error of 180° on the azimuth circle from the true meridian.

To that mean point, deduced from these observations, the instrument must now be turned; and fixed there till the proper correction can be applied to it. Upon the telescope being turned down to the horizon each way, it may be observed what distinct object there may be either to the north or south that coincides with one of the perpendicular wires; or if no such object should occur, a mark may be placed each way, or either way, to which to keep the instrument, till the correction can be investigated, which is requisite on account of the change of the sun's declination during the interval between the morning and evening observations; for any alteration in his declination will affect the azimuth deduced in this way, as it does the hour; and neither of those corrections can be ascertained till the latitude of the station be known.

Yet may the latitude be now deduced, with fully sufficient accuracy for that purpose, by observing the passage of any one known star over the meridian, and reading off its altitude and zenith distance. The pole star, or any star of the first or second magnitude, will be found visible in the day-time with the telescope of this instrument; and the latitude being, though roughly, deduced from it, the correction for time may be sought in the usual way. That required for azimuth may as easily be investigated by this very simple formula, which the late Mr Wales constructed for this purpose."

Take the daily variation of the sun's declination from the Nautical Almanac. Then say, As 24^h is to half the interval between the observations, so is the daily change in the declination to its change in that half interval. Turn the half interval into degrees, minutes, and seconds; and reduce the change in that half interval to seconds. Then to the log. of the change so found add log. cosecant of half intervals + log. secant of the latitude of the station, the sum will be the log. of the correction in azimuth in seconds to be applied to the middle point. This will fall to the west of the true south point when the sun is advancing towards the north pole, and *vice versa* east when he is receding from it.

"Having calculated the necessary correction, you may then apply it to the azimuth before deduced, from a mean of the observations; and shift the instrument just that quantity, as shewn on the azimuth circle. Then clamping it firmly there with both of the side clamps, you may trust to its remaining in that position as far as the instrument itself is concerned; for when once those clamps are set, the tangent-screw for adjustment has no power over it.

Thus it becomes, to all intents and purposes, so far as its situation and size permit, a transit circle; placed very nearly, if not quite truly, in the meridian, from one day's observation alone; and ready for making some observations in that first evening.

The chronometer having been let go down, may have altered its rate, which as yet will be uncertain; though if the watch be good, that rate will not be unsteady. Its error at noon was known from the corresponding altitudes; and any observations of the evening may afterwards be reduced to the real time, when the rate becomes known. The passage of stars over the meridian, even in this first evening, will therefore be valuable; and if the moon should be among the number, an observation of her passage, and a comparison of it with that of a star nearly of the same declination, will already give great insight into the longitude of the station. The error of the instrument in collimation of altitude must be known, before the exact latitude can be ascertained; but as that error is not apt to vary even by carriage, the latitude may be confided in, within 10″, from the observations of the same evening.

By repeating the same process, either in whole or in part, as he may judge necessary, the next day, he will verify his meridian, or bring it still more near to the truth. He will obtain the rate of his time-keeper; and begin to feel a degree of confidence. For when once he has a mark in the meridian to which to re-adjust his telescope, he may, if he finds occasion, release the instrument, and turn it in any direction for other observations, knowing that he can replace it at pleasure. Yet must it be said, that in all instruments, the less they are moved out of any position, and their adjustments disturbed, the better they will always perform what is expected from them.

Another method there is, which has not often been practised, though it was found very convenient to General

Roy in his trigonometrical measurements; the calculating of the exact time and distance of the pole star from the meridian, when it is at its greatest elongation east or west; and by adjusting the instrument to it at that time, reading off the azimuth on its circle. After this, correcting the distance of the star from the pole by the co-sine of the latitude of the station, you will have the true azimuth of the star; the difference of which, from the azimuth observed on your circle, will give you the deviation of it from the true meridian. This does not require the time to be known or attended to with very great precision; because the motion of the star in azimuth is very slow indeed. And since it comes both to the east and west of the meridian in the space of every twelve hours, two opportunities of this kind offer every day.

Another method, where you have the time sufficiently correct, is, to calculate the meridian passage of the pole star above or below the pole. This occurs nearly six hours after the other; when, pointing the telescope of the instrument to the star, and following it in its slow motion, covered or bisected by the meridian wire, till the exact instant it is to come on the meridian, then clamping the instrument there, it will be found very nearly in the meridian indeed. If all the adjustments of your instrument are right, you will probably find it err but a few tenths of a second of time in respect of stars observed afterwards within the tropics.

These are methods of finding a meridian which seem best to be recommended with such an instrument; which, describing true verticals and horizontals, and giving the angles of elevation in the one and azimuths in the other, has all the requisites for such a purpose; and is itself a transit instrument encompassed by a circle, or a small portable *transit circle*, ready for meridional observations as soon as its true position is ascertained.

For the verifying of this position, or bringing it strictly to the truth, two methods may next be recommended: the one by the meridian observation of any circumpolar star above and below the pole; the other by the observation of two well-known stars over the meridian which differ considerably from each other in elevation, and observing how far the times of their passage differ respectively from the exact time of each by strict calculation."

We shall have occasion to consider these methods more at length under TRANSIT INSTRUMENT.

CHAP. III.

On the Repeating Circle.

SECT. I. *Description of Troughton's Repeating Circle.*

Repeating circle.

THE principle to which the repeating circle owes its existence, was discovered by Professor Mayer of Gottingen. That learned and laborious astronomer, in the year 1758, communicated his invention to the Royal Society of that city, in a memoir upon an instrument which he calls a goniometer, the principles of which he had mentioned to other astronomers eight years before. The goniometer was intended for observing angular distances between terrestrial objects in land surveying; and, although far from being well contrived for the purpose, it was capable of performing this much better than any instrument known at that time.

Description of Mayer's goniometer.

It consisted of two bars of about a foot in length; the lower one was attached to a stand and socket like a common theodolite, and capable of being turned round, or set fast at pleasure. The upper bar was connected by centre work to the lower, upon which it turned all round, and carried along with it a telescope, with cross wires for observation. The instrument had no divided limb, instead of which, upon the end of each ruler, was made a fine dot, and the angle by which the bars opened was measured, by taking off the distance between the dots in a pair of compasses, the angular value of which was ascertained on a line of chords of a proper radius, diagonally divided to the exactness of 2′. As the two bars were required to be moved quite round upon each other, the two dots could not lie precisely in the same plane, and of course their exact coincidence could not be determined. This error, therefore, as well as that of the collimation of the telescope, required some kind of artifice to remove. This was neatly done, by throwing these errors back into an angle on the outside of the real point of commencement, as will appear in the following example of the use of the instrument.

Method of using Mayer's goniometer.

Bisect with the wire of the telescope the object to the left, having the lower bar pointed a little more to that hand, and made fast to the stand. Now carry forwards the telescope, by opening the angle between the bars, and bisect the object to the right. The opening between the bars must now be taken in the compasses, and its value ascertained by the scale, which suppose to be 45°. With this distance unaltered, carry the instrument backward round the socket of the stand, until it again bisect the object on the left, and again by opening the bars, make the telescope bisect the object on the right. The angular opening of the bars must now again be ascertained as before, which suppose to be 75°. It is obvious, that this last quantity is twice the distance of the objects and the exterior angle, and that the former was the angular distance and exterior angle; therefore their difference 30° is the approximate angle between the objects, and this angle taken from the first measured quantity leaves the exterior angle 15°. This last quantity enables us to ascertain the point of commencement besides, and we have proceeded two steps in the business of repetition. The observations must now be continued, by turning the instrument backwards round the socket to bisect the object to the left, and the telescope alone must be carried forward to bisect the object on the right, and so on alternately until a great number of observations have been made; but care must be taken, that however often the bars are carried round, the operations may finish, when they are in a position that their angle may be measured with the compasses. Suppose we leave off when the instrument has gone through nearly a revolution, and that the opening of the bars is found to measure 44° 50′, this quantity, as well as 15°, the value of the exterior angle, taken from 360°, leaves for the whole amount of 10 repetitions 300° 10′, and this divided by the number gives 30° 1′ for the true angle. Some knowledge of the approximate angle is useful, to prevent the division being made by a wrong number, in cases where the repetition has been long continued. The intermediate sights, provided they are well taken, do not at all affect the result, and no error of the instrument is charged upon the total angle but those of the commencing and ending points; and whatever the errors of these may be, by long continued observation they may be almost annihilated. With this instrument, therefore, and indeed the same may be said of all the repeaters, the patient perseverance of the observer becomes the measure of the accuracy of results obtained by them.

Thus much we have thought proper to say respecting the goniometer, which, although certainly not a circle, belongs to the class of repeaters, and was the original step which led to the construction of the celebrated instrument, which is the more immediate subject of our present enquiries.

When Hadley's octant became known to the world, Professor Mayer was among those who rightly appreciated its valuable properties, and by extending its arc to a complete circle, for the purpose of reducing the errors of division, he gave it the repeating property of his goniometer, which he had before perhaps only thought of. The Professor was fully aware, that the common theodolite, and other surveying instruments, were capable of being used as repeaters; and we can assign no other reason for his giving the preference to the undivided bars, diagonal scale and compasses, than that scales must at that time have been more accurately divided than circles.

It was about the year 1789, when Borda first caused a repeating circle to be constructed for astronomical and geodetic purposes; and one of our motives for being so particular in what is said before, was to shew exactly how much is due to him. The former repeaters, it has been seen, gave but one result for two operations; but by the use of an additional telescope, applied as hereafter to be described, he procured the means of obtaining double results, but this advantage is not purchased at a less expence than three distinct operations. The astronomers of the continent of Europe, and particularly in France, where the art of dividing, except of kingdoms, is almost unknown, have been lavish of their praises of this instrument; while in this country, where that art is practised with equal success upon minuter objects, a prejudice against it has too long continued. As a proof of this, we believe that the late Mr Ramsden never made either a reflecting or a repeating circle. The prejudice is now, however fast wearing off, and this circle begins to take that rank among our instruments to which its merit entitles it. This we think will appear on perusing the following description, and from the examples as communicated by different observers.

Repeating circle. PLATE CXLVII.

Plate CXLVII. is a perspective representation of the repeating circle as made in London, and exhibits, for ought we know, as perfect a construction of that instrument as has yet appeared. In our description of it we shall, as we proceed, occasionally remark upon the difference between it and those made abroad, of which this professes to be in many respects a copy.

At bottom, a strong tripod with feet screws rests upon a pedestal. Two of the screws bear upon the concave tops of two plain brass studs, which are affixed to the pedestal, but the other screw rests upon an apparatus, whereby an exceeding slow motion is communicated to the instrument. This is represented at *a*. A steel spindle 15 inches long, a full inch in diameter at one end, and somewhat more than half as much at the other, has its thicker end inserted into the middle of the tripod, to which it stands perpendicular. This spindle or axis is worked, especially near the ends, with the most scrupulous attention to truth. A strong hollow brass pillar is nicely centered upon the extreme ends of the spindle, round which it turns with a free and steady motion, and resting with its base upon the middle of the tripod, sustains the whole weight of the incumbent instrument.

The azimuth circle 12 inches in diameter, united by 6 radii and a circular centre-piece to the pillar, moves round with it near to the upper surface of the tripod, but yet without touching it. This circle is graduated by lines into parts of 10′ each, which are met, and subdivided to 10″, by a vernier, as at *b*, attached to each branch of the tripod. All this is executed with the greatest care, in order that an angle may be well ascertained by a single observation, in cases where extreme accuracy is not wanted; and as the business of repeating is a very laborious task, and productive of a vast waste of time, this substitute will be considered by most observers as a very convenient relief. It may here be noticed, that, as the position of the telescope is fully three inches from the vertical axis, all angles, except in astronomy, and where land objects are very remote, must be subjected to a consequent correction, in proportion to the distance of the objects from the station.

The advantage of three readings over two for the limb of a theodolite, the telescope of which will turn quite round, is great, and was perhaps first noticed by Mr Pond. In two reverse positions of the circle, made by turning the telescope half round in azimuth, and also half round its own axis, three verniers will give the position of an object upon six different and distant portions of the circle; but where two opposite verniers are used, no more than two places of the circle are employed, for on reversion the verniers only exchange positions. A screw apparatus, as at *c*, attached to one of the branches of the tripod, clamps the azimuth circle, or allows it a quick or slow motion at pleasure.

The repeating circle of Borda has an azimuth circle of about four inches diameter, the single vernier of which subdivides it to 3′ or 5′: the edge is indented, and acted on by a pinion, for the purpose of turning it round, in the same manner that similar means are employed in the common theodolite.

To the top of the pillar is horizontally fixed a strong brass bar *d*, upon which a similar bar is laid, and secured there by two finger screws, the head of one of which is represented at *e*: this is the part where the instrument may be taken asunder for packing, or for more conveniently moving it from place to place. At right angles to the bars, and fastened to the upper one, are erected two supporters, in the tops of which are centered the ends of a horizontal axis, round which the whole of the upper part of the instrument may be turned. A semicircle *f* is fastened at its centre, to one end of this axis, and having its position parallel and contiguous to the interior side of one of the supporters, is occasionally laid hold of by a clamp attached to the latter, and thus affords the means of securing the principal circle and telescopes in any position that observations can require.

The centre-work of the upper circle is made fast to the middle of the horizontal axis, which it crosses at right angles; at its remote end, upon the socket of the centre, is placed a cylindrical counterpoise, which balancing the circle and telescopes, keeps them, respecting motion round the cross axis, at rest in every position. The counterpoise, in order to give it a maximum effect, is fixed at the greatest distance from the cross axis, which will allow it to pass the bar on the top of the pillar, when the face of the circle is put horizontal, or in changing its position from one side of the pillar to the other.

The principal circle is 18 inches in diameter, composed of an octagonal centre piece, into which are inserted eight conical radii; these being strong and tubular, are united at their extremities by a circular limb; strengthened in its place by a rim or hoop, which being screwed fast to its back, forms what is termed an *edge-bar*: the division of the circle is by lines, the distance between which is 10′.

To the back of the octagonal centre piece is screwed the axis whereon the circle and telescopes are turned round in the plane of the circle: it is nearly eight inches long, but only about two thirds of its length is employed for that purpose, working in the socket of the counterpoise; the rest forms a bearing round which the socket of the back telescope revolves.

Plate CXLVII.

An index with four branches, the verniers of which subdivide the circle to 10″, has an axis of steel attached to its centre, which passes through the whole length of the axis of the circle, the latter being a socket wherein it turns round, in the same manner that the axis of the circle turns in the socket of the counterpoise. This index is furnished with the usual apparatus for quick and slow motion, which attaches to, and forms a part of, its chief branch, as at *g*. There is another index, the position of which is behind the circle, having but one branch, and which carries no vernier; it is furnished with the means of being clamped, and put in gradual motion like the other: in clamping it attaches to the *edge-bar* of the circle: it is united to a socket, which embraces the part of the axis of the circle not occupied by the socket of the counterpoise.

The instrument has two telescopes similar to each other in almost every respect. The one in front of the circle is fixed to the index at half right-angles between two of its four branches; the one behind has a position forming the same angle with the only branch of the other index. The connection between the telescopes and indices is formed near the centres, so that the former may take the unbiassed direction which is produced by the axis alone, without being at all influenced by the irregularities of the limb. In the circles of Borda, the telescopes are made to take the direction of the circle, and the accuracy of their motions depends upon the truth of its plane. These telescopes are about two feet in length; the aperture of the object-glasses nearly an inch and three quarters, and they are provided with powers of from 30 to 60, according to their different eye-pieces. The telescope behind the circle has, in its form, only two cross lines: the plate in which they are fixed is adjustable respecting the vertical and horizontal position of the lines, and is also acted on by two drawing screws for placing the line of collimation parallel to the plane of the circle: two others at right-angles draw also, and are intended for placing the collimation parallel to a level, which is to be described. In the front telescope there are three lines crossing other three; these are adjustable exactly like the former, only the adjustment last mentioned is not necessary. As the telescopes of the repeating circle are designed to view objects very differently situated respecting distance, the eye-tubes of both have a motion given them, by teeth and pinions, whereby they may be brought outwards, in order to procure distinct vision of near objects.

Between the two portions of the axis of the circle, namely, that which works in the socket of the counterpoise, and that upon which the socket of the back telescope turns, there is securely united to the axis a wheel of about two inches diameter, the edge of which is surrounded by a circle cut into three pieces, and again joined at two places in the same manner as the links of a watch chain, and at the third by a clamping screw, which is seen in the Figure at *h*. To the middle piece of the cut circle, and opposite to the screw, is fixed an ear extending about five inches from the centre, and upon the front of the horizontal axis, a similar one is fixed: these two ears are connected by an adjusting screw, which, when the jointed circle is made by its screw to embrace the axis, furnishes the means of gradual motion to the circle and telescopes; but when the axis is released from the action of the clamp, the general motion is free. The apparatus last described is very superior to the means which Borda employed for accomplishing the same object. In the French construction, a wheel of about five inches diameter, with an indented edge, is fixed, beyond the remote end of the counterpoising cylinder, to the axis of the circle, and is acted on by an *endless screw*, which, for the sake of quick and slow motion, is thrown off and and on at pleasure. This screw, owing to its great distance from the parts which require its use, (the circle and telescopes,) must twist the centre work, and of course leave the parts at liberty to move after its action ought to have ceased; an impediment which, if not a very dangerous, is at least a very troublesome one, and productive of much loss of time.

Plate CXLVII.

For astronomical purposes, the telescope behind is of no use, instead of which a level is employed; and in order that it should apply immediately to its work, it is fixed, not upon the stand, which is the usual application, but upon the back index of the circle, and has the advantage of its quick and slow moving screws. The position of the back telescope being of necessity eccentric, the level is placed parallel to it on the opposite side of the axis, and becomes a counterpoise to the telescope, for which purpose it is made rather heavier than is otherwise required. The tube of this level is ground inside to a radius, which gives the bubble a range of about an inch and a half to a minute. Two ivory divided scales are placed over the tube, which indicate single seconds, and by which the position of the index is ascertained to about double that quantity.

Another level, the use of which regards the plane of the vertical circle, has one end affixed to the cross axis, and the other to the counterpoising cylinder: if, when that plane is adjusted perpendicular, the level is brought to the middle, it will, in future, ascertain the true position without having recourse to the original adjustment.

The upper part of the back index is formed into a semicircle of about half the radius of the circle itself, and upon the fore part of it are roughly divided two quadrants of zenith distance, and a blank of about half an inch separates their *zeros* from each other. Two small sliders, one of which is seen at *i*, are made to fit the arc of the semicircle, and their fiducial edges may be set so as to point to any division. To the object end of the fore telescope is occasionally attached an index *j*, which reaches down to the divisions of the semicircles, and at that end covers the space between the *zeros*. By this contrivance, when the sliders are set to the approximate zenith distance of a heavenly body about to be observed by repetition, the sliders and indices will touch each other at their relative positions, so as to stop the telescope at the proper point upon the limb for finding the object, near the centre of the field of view.

The azimuth motion has also its stops; a small cylinder of steel, pointed at one end, is lodged in a piece of brass, and urged forwards by the force of a spiral spring against the edge of the azimuth circle when used, but at other times it is put out of action. When the leading vernier of the circle shews 360° or 180°, the pointed end enters a shallow hole, which, for that purpose, is made in the edge of the circle, but so as only just to be felt on turning it round; for the point will retire of itself when a slight additional pressure is applied, and then it allows the instrument to turn freely round. With these contrivances, a bright object may, by repetition, be observed in the day time, or a faint one by night, the former without fear of losing it, and the latter without danger of mistaking another for it; and that without having recourse to the divisions at all during the intermediate observations.

An index carrying a microscope at each end, one of which is shewn at k, is applied to the centre of the fore index, by the help of which the four verniers are read; that is, two of them by each, for one will not read all the four, because the arm cannot pass the telescope. A similar arm is centred upon the base of the pillar, which, moving freely all round, its single microscope serves to read off all the three verniers of the azimuth circle.

Adjustments of the repeating circle.

Having now gone through the description of the repeating circle, it only remains that there should be given an enumeration of its few and simple adjustments. 1st, The azimuth axis is adjusted vertical, or the circle horizontal, by means of the feet screws and levels in the way practised in the corresponding adjustment of other instruments. 2d, The plane of the upper circle is adjusted vertical for astronomical purposes, by turning it round the cross axis; and the required position is ascertained by applying a plumb-line to the face of the circle. This adjustment is, however, obtained much more correctly, by observing any elevated object at rest, pointing the telescope upon it directly, and then observing its image as reflected from the surface of a fluid: the middle vertical wire bisecting, in both cases, is the proof of adjustment, and furnishes an unexceptionable criterion. 3d, The line of collimation of the telescope parallel to the plane of the circle. As both the telescopes have their positions eccentric, respecting the vertical axis, chuse, for this purpose, a very distant object, and as nearly as can be estimated in the horizon; bisect that object by the middle vertical wire, and then read off what the verniers of the azimuth circle give; now turn the face of the circle to the contrary hand, bisect the object in this position, and read the azimuth circle a second time; now carry the instrument in azimuth through half the angular difference, (abating 180°), as shewn at the two positions, and then the plane of the circle will pass exactly through the object; move now the wires of both telescopes by their proper screws, until they bisect the object. The fourth adjustment is of use only, when taking levels is the end of observation; it is to set the line of collimation of the back telescope parallel to the level; a very distant object is also required for this purpose, because the back telescope is lower in position than the front one. With every thing adjusted as before, bisect any object nearly in the horizon by the middle horizontal wire of the fore telescope, and read the divisions of the circle; reverse the instrument, both in altitude and azimuth, and bisect the object, and read the circle as before. The half difference of the readings will be the altitude or depression of the object; set the indices, therefore, to this half difference, and turning the instrument round in azimuth, look for a new object that is bisected by the wire; this object will be in the horizon, and the end will be accomplished by turning the back index until the level comes to the middle, and adjusting the horizontal wire by the proper screw, so that it may bisect that object.

The perspective view of the repeating circle shews all that is provided by the maker, and in the observatory is all that can be required; but in the field, as no one would think of placing it upon the ground, a stand is wanting; but this may be so simple in its construction, as to be made by any one accustomed to work in wood. It should consist of three spreading well braced legs, inserted at top into the under side of a round table, and united below by three crosses, reaching from leg to leg. The diameter of the table should be at least two inches greater than is required by the feet-screws of the tripod. It may be about three feet high, more or less, according to the stature of the observer; and if a circular groove in the surface of the table receives the feet-screws, the three studs may be dispensed with, and the whole instrument turned round in order to lay it in the plane of every pair of objects, the angular distance of which is to be taken at the same station; and that without losing the angular point, as indicated by a plummet suspended below the centre of the instrument.

There will seldom be found ground sufficiently firm to support the weight of the observer, without deranging the position of an instrument as he walks round it; and on this account, in the most accurate operations, it is usual to level the ground, and to secure steadiness by driving three piles of wood to a sufficient depth for the legs of the stand to rest on.

As perhaps the feet-screws of every instrument are the most unsteady parts, for the purpose of lessening this evil, these are made as short as possible. An observer, therefore, should provide himself with a number of wedges for propping the tripod, in adjusting the circle into the proper plane, agreeable to a rule hereafter to be given.

SECT. II. *On the method of observing Terrestrial Angles with the Repeating Circle.*

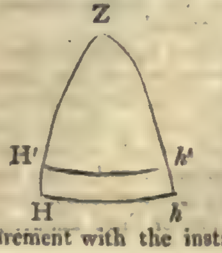
Method of observing terrestrial angles with the repeating circle.

The repeating circle, as above described, may be considered either as a geodetical or as an astronomical instrument; and it owes much of its celebrity to its having been employed in this double capacity by the French astronomers, in the great trigonometrical operations lately carried on in that kingdom.

Of the manner in which the repeating circle was used on this occasion, a most ample account has been given by the National Institute, in two quarto volumes, entitled *L'arc du Meridien.* Much useful information may likewise be found in Puissant's *Geodosie*, and in a single quarto volume, published separately by Delambre, entitled, *Methodes analytiques pour la Determination d'un arc du Meridien.*

In all these treatises, a great portion is allotted to calculations which become necessary, both from the mechanical construction of the repeating circle, and from the circumstances under which it must frequently be unavoidably used. Many of these considerations, being common to all instruments, will be given under SURVEYING. And of those which are peculiar to this instrument, our limits oblige us to omit a great many, and to confine ourselves to those which seem to us most likely to be of general utility.

The repeating circle will not measure the horizontal angle between two objects of different elevations, but it will measure the direct angular distance between two objects, and the zenith distance of each of them, from which data, the horizontal angle may be inferred by spherical trigonometry; and as, in each of these measurements, the repeating property of the instrument may advantageously be employed; the horizontal angle may no doubt be obtained to a very great degree of precision.



Let Hh be an arc of the horizon, H′, h' two terrestrial objects. Z the zenith, and ZH, Zh great circles of the sphere passing from the zenith to the horizon through the points H′, h'. Then in the triangle ZH′h', the three sides ZH′, Zh', H′h', being determined by actual measurement with the instrument; the angle Z, equal to the arc H *h*, may be computed by spherical trigonometry. The problem is very nearly, indeed, similar to the well-known case in nautical astronomy, in which it is required to determine the true distance of a star from the moon, having given its apparent distance, and the altitude of each by observation; and for each process, Tables have been devised to facilitate the calculation, which, without such aid, would be very tedious and laborious. The zenith distance of a terrestrial object being determined with this instrument, precisely in the same manner as the zenith distance of a star or other celestial body, nothing here need be said on that part of the process. We shall, however, subjoin an example actually taken by an instrument of Mr Troughton's construction, to shew with what extreme accuracy a result may be obtained by an experienced observer.

Zenith distances of a fixed mark, taken Sept. 4, 1812, with a repeating circle of Mr Troughton's construction.

			Angle given by each successive pair of observations.
Zenith distance given by	2 observations	92° 45′ 3″.2	92° 45′ 3″.2
			— — 6″.3
	4	— — 4″.8	
			— — 9″.4
	6	— — 6″.3	
			— — 8″.3
	8	— — 6″.8	
			— — 10.″4
	10	— — 7″.5	
			— — 4″.0
	12	— — 6″.9	
			— — 8″.7
	14	— — 7″.2	
			— — 5″.2
	16	— — 6″.9	
			— — 8″.7
	18	— — 7″.1	
			— — 5″.9
	20	— — 7″.0	
			— — 8″.7
	22	— — 7″.2	
			— — 3″.1
	24	— — 6″.8	
Mean of the twelve angles given by each successive pair of observations			92° 45′ 6″.8

In making the above observations the light was favourable, being steady and uniform; the sun was always hid.

The mark exceeded the wire some seconds on each side, and was not so round as could have been wished. A mark smaller and perfectly round might probably have been bisected more exactly.

In the 24th observation the day light began to fade, and it was apprehended that this observation was rather less exact than the preceding ones.

There is every reason to suppose, that in the above experiment the zenith distance of the signal was obtained within a small fraction of a second.

To observe the angle between two signals, the plane of the instrument must first be brought into the plane of the two objects. To accomplish this, first set the tripod of the instrument, with one of its feet as near as you can guess, in a line with that object, which of the two you judge to be nearest to the horizon; and, with the plane of the circle vertical, and the lower telescope horizontal, (both to the exactness of two or three minutes,) bring the telescope to the object, partly by turning in azimuth, and partly by screwing the foot screw; next turn the circle round upon the cross axis of the stand, until it seems by the eye to occupy the proper position, then a second time bring the telescope to the object, by the foot screw and turning in azimuth; lastly, complete the operation by bringing the upper telescope to the other object, by its own proper motion, in conjunction with that of turning round the cross axis. The principle of the above rule is this; the cross axis of the stand and the lower telescope being made parallel, and pointed to the object, the circle may be turned round that axis without changing the angular position of the telescope. When this verification is rightly performed, the intersection of the wires of the micrometer of the moveable telescope should pass over each object in its revolution round its centre. To effect this readily requires some little dexterity and practice.

The following example was likewise taken by an instrument made by Mr Troughton.

No. of Obs.	Angle by Inst.	Angle deduced.
2	127° 7′ 45″	63° 33′ 52.5″
4	254 15 24	63 33 51.0
6	21 23 00	63 33 50.0
8	148 30 30	63 33 48.7
10	275 38 10	63 33 49.3
12	42 45 50	63 33 49.1
14	169 53 20	63 33 48.6
16	297 00 50	63 33 48.5
20	191 16 17	63 33 49.0

The angle thus measured requires to be corrected for the eccentricity of the lower telescope; and this correction depends on the distance of the objects from the observer, and upon the distance of the axis of vision of the lower telescope from the centre of the instrument.

In circles constructed by Mr Troughton, the eccentricity of the lower telescope is one inch and four tenths; and the following Table is calculated upon this supposition from Delambre's formula given in *L'Arc du Meridien*.

Fathoms.	
1000	2.″00
2000	1.00
3000	0.67
4000	0.50
5000	0.40
6000	0.33
7000	0.30
8000	0.25
9000	0 22
10,000	0.20
11,000	0.18
12,000	0.16
13,000	0.14
14,000	0.13
15,000	0.13
16,000	0.12
17,000	0.12
18,000	0.11
19,000	0.10
20.000	0.10
21,000	0.10
22,000	0.09
23,000	0.09
24,000	0.08
25,000	0.08

Use of the above Table.

With the distance of the object which is on the same side as the eccentric telescope, that is, the distance of the left hand object in our instruments, enter the Table and take a correction, to which you prefix the sign +; with the distance of the right hand object, take a second correction, which is to have the sign minus —.

Example. Suppose the distance of the left hand object to be 5000 fathoms, and the right hand object to be distant 22,000 fathoms, and the eccentricity to the left;

	Fathoms.	
Dist. of object to the left	5000	+ 0″.40
. . . . right	22,000	— 0″.09
Total corrrection		+ 0″.31

The above correction arises from the mechanical construction of the instrument; but the principal correction is to reduce the observed oblique angle to the horizontal angle, for which purpose the subjoined Tables are added. They were calculated by the French astronomers, who have endeavoured by every means in their power to extend and facilitate the use of this valuable instrument.

Let A = the angle of position, or the observed angle.
H = the altitude of the signal A.
h = the altitude of the signal B.

Let $n = \sin.^2 \tfrac{1}{2}(H+h) \text{ tang. } \tfrac{1}{2} A - \sin.^2 \tfrac{1}{2}(H-h) \cot. \tfrac{1}{2} A$.

Then the cor. $x = n$, sec. H, sec. h.

If the zenith distances differ more than 2° or 3° from 90°, the following formula may be employed.

$$\text{Sin.}\tfrac{1}{2}z = \sqrt{\frac{\sin.\left(\frac{C+\partial+\partial'}{2}-\partial\right)\sin.\left(\frac{C+\partial+\partial'}{2}-\partial'\right)}{\sin.\partial - \sin.\partial'}}$$

z being the angle reduced to the horizon, C the angle at the centre, ∂ and ∂' the zenith distances of the signals.

To facilitate this reduction, we have added the tables calculated for this purpose by M. Delambre. By these tables we may at the same time reduce the horizontal angle to that formed by the chords.

The use of these tables will be easily understood by an example.

H + h is the sum of the zenith distances of the observed objects diminished by 180°.

If the sum should be less than 180°, H + h is the remainder required to complete 180°.

H — h is always the difference between the two zenith distances.

(H + h) and (H — h) are always considered as positive numbers.

P + Q is the sum of the distances in French toises between the observer and each of the signals.

P — Q is the difference between these distances; (P — Q) is always positive.

With (P + Q) and (P — Q) take in Tab. II. two numbers, to which you always must annex the sign.

With the observed angle, take in Tab. IV. the number, *Tangent*, to which the sign + must be always annexed, and which must be placed under the factor found by H + h.

With the same angle take in the adjoining column, *Cotangent*, to which annex sign —, and place it under the factor found by H — h. Place these same numbers under the factors (P + Q) and (P — Q), as in the example. Make the four requisite multiplications.

The difference of the two first products is the reduction to the horizon, to be applied according to its sign.

The difference of the two last products is the reduction to the chords, to be applied with its proper sign to the horizontal angle.

This last reduction is almost always subtractive, but it sometimes becomes additive, by the fourth product exceeding the third.

In general, the fourth product is nothing, and the third always very small; so that in calculating the reduction, which is indispensable, it is very little more trouble to reduce the angles to the chords. These tables are, in general, quite sufficient for the reduction to the horizon; but, for greater exactness, Table III. is added. The difference of the products, as obtained above, may, by means of this table, be multiplied by sec. H, sec. h, as required by the formula. If greater precision be required, the whole calculation may be repeated with the corrected angle, instead of the observed angle.

To make use of this table, it is necessary to have a plan of the triangles with a scale. The arguments are on one side of the triangle as a base, and the height.

Example.

Observed Angle.	Zenith Distance.	Distance of Signals, in Toises.
32° 20′ 15″.7	A = 89° 41′ 54″.6	A = 18283
	B = 88 49 15.6	B = 24423.

	— Cot.	+ Tang.	D. M. Angle.		— Cot	+ Tang.	D. M. Angle.

It has been shewn, how, from the oblique angle of two objects, A and B, as seen from a point C, we can obtain the horizontal or azimuthal angle; but it is necessary, for the truth of our conclusion, that the point C remain the same for the zenith distance observations as for the oblique angles. If we examine the construction of the repeating circle, we shall find that its centre C is lower in the vertical than in the horizontal position: this circumstance seems to have been overlooked by the French astronomers; or they have probably included it in the requisite correction employed for the difference of height of the signal above the centre of the circle. To apply this correction, we are to consider what would be the zenith distance of an object if the centre of the instrument were elevated or depressed a given quantity.

The correction is as follows:

Let *d* H be the difference of altitude of the two positions, D the distance of the observed signal, ∂ the zenith distance required to be corrected; then the corrected distance will be

$$\partial + \left(\frac{\partial H}{D}\right)\frac{\sin.\partial}{\sin.1''}$$

If the instrument is advanced before the signal, the distance corrected will be

$$\partial + \left(\frac{r}{D}\right)\frac{\cos.\partial}{\sin.1''};$$

r being the distance of the centre.

In Mr Troughton's circles the centre of the circle is 5.4 or 5.5 inches lower in the vertical than in the horizontal position.

SECT. III. *On the Use of the Repeating Circle as an Astronomical Instrument.*

Use of the repeating circle as an astronomical instrument.

We have seen that the principal advantage of the repeating circle consists in the contrivance by which the angular distance of two points may be measured with extreme accuracy. Now, it is evident, that if we could always command a visible terrestrial object, placed exactly either in the north or south point of the horizon, and if at the same time a star could remain stationary on the meridian, its meridian altitude might be obtained by the process above described, without farther explanation; for the angular distance between the star and the terrestrial object would be the meridian altitude required. But neither of these conditions can be obtained. The stars are apparently in constant motion; and a terrestrial object as above defined, (even if it could be obtained,) would be invisible by night; hence arise two difficulties, the one produced by the motion of the star, and capable of being obviated by appropriate tables, the other is remedied by substituting a spirit level instead of the back telescope. This substitution will effect some little change in the mode of observing which we shall shortly describe, and will require some few additional verifications, (see page 501, col. 1.) of which the following are the most essential.

Verification of the Verniers.

Verification of the verniers.

Call the vernier which is connected with the clamp-screw No. 1, the others No. 2, No. 3, No. 4, in succession, according to the divisions of the circle. Place No. 1. at zero, read off all the others, and set down their deviations with the sign + or —, as they exceed or fall short of their respective divisions, add these quantities, and divide the sum by 4. This quotient may be called the index error, and must be applied to the observed angle with a contrary sign. For example,

No. 1. . . . . 00"
2. . . . . + 05
3. . . . . + 10
4. . . . . − 3

4) + 12

+ 3" Index error to be subtracted from the observed angle: then suppose at the end of an observation that the verniers stand thus:

No. 1. . . . . 183° 14 10"
2. . . . 7
3. . . . 14
4. . . . 20

4) 51

183 14 12.77
Deduct the Index error − 3

True angle 183 14 9.77

As the level and the front telescope turn round one common axis, independent of each other, it should be remembered, that the circle must always be fixed to, and form one piece with one of the other two. In the front observation which begins the series, it must be considered as forming one piece with the front telescope, and care must be taken on no account to touch the screw that alters their relative position to each other. On the contrary, in the reverse observation, the circle must be considered as forming one piece with the level, and equal care taken not to separate them from their fixed position. The great danger to an unexperienced observer with this instrument is, that his whole series of observations may be destroyed by improperly releasing the piece which ought to remain fixed.

But a little consideration and practice will render this operation easy and familiar.

A well regulated clock or watch is necessary for these observations; and they will be rendered much easier, if an assistant attends to the level, while the observer bisects the star.

It may not be improper to remark, that it is of more importance to make good observations, than to make a great number. The errors of division are so small in our best constructed instruments, that a very few repetitions will render their effect quite insensible. The observer will soon find that it is the error of observation he has to contend with, arising from the smallness of the radius, and want of power in the telescope; for this reason, the observations should not be hurried, but sufficient time allowed for examining the true position of the level and the accurate bisection of the star.

The corrections to be applied to the observations made with the repeating circle are, for the purpose of reducing the meridian altitude, from that observed a short time before or after the passage of the star over the meridian. The hour angle, or distance of the star from the meridian, must, therefore, be correctly known; and in proportion as the rate of the clock is well ascertained, may the observations be extended with confidence on each side of the meridian.

The pole-star, from the slowness of its motion, being the best adapted for observation with this instrument, we have given a table of corrections for that particular star, extending to half an hour from the meridian, beyond which the observations should never extend. This table having been calculated for the latitude of Paris some years since, the numbers must now for the latitude of Greenwich be diminished $\frac{1}{10}$th, that is, the whole correction multiplied by 0.95; and for the inferior passage of the star the whole correction must be multiplied by 0.88.

Tables II. and III. are general tables for any star, and for any latitude; they were calculated by Delambre from the following formula:

Make $P =$ The hour angle.
$L =$ Latitude.
$D =$ Declination of the star.
$x =$ Corrections required.

If the star pass southward of the zenith $x = -\frac{2\sin.^2\frac{1}{2}P, \cos. D, \cos. L}{\sin.(L-D)\sin. 1''} \cdot \frac{1}{2}\left(\frac{2\sin.^4\frac{1}{2}P, \cos. D, \cos. L}{\sin. L-D \sin. 1''}\right)^2 \cot. L-D \sin. 1''$.

If the declination be south, change the sign of D.

If the star passes to the north of the zenith, for $L-D$ substitute $D-L$, and change the sign of the terms.

But if the star passes below the pole, $D+L$ must be substituted for $D-L$, the signs remaining the same.

The numbers contained in these tables are the factors $\frac{2\sin.^2\frac{1}{2}P}{\sin. 1''}$, and $\frac{2\sin.^4\frac{1}{2}P}{\sin. 1''}$, the remainder of the calculation is thus reduced to finding the value of the other factors.

$$\left(\frac{\cos. D, \cos. L}{\sin. D-L}\right) = F,$$

and

$$\left(\frac{\cos. D, \cos. L}{\sin. D-L}\right)^2 \cot. D-L = f.$$

SECT. IV. *On the Use of the Repeating Circle as a Meridian Circle, when its repeating Property is dispensed with, but the Errors of Division equally done away.*

New method of using the repeating circle.

As the French astronomers have never used this instrument but in the manner above mentioned, it is not perhaps generally known, that it may be employed as a meridian instrument to determine the declinations of stars, without recurring to its property of repeating; and we are permitted, on the authority of the astronomer royal, to state it as his opinion, that, when so employed, it is the most perfect portable instrument of its size hitherto constructed. When placed in the plane of the meridian, and there suffered to remain till a series of observations on many stars is completed, it will very nearly resemble, in its mode of action, the mural circle lately erected by Mr Troughton at Greenwich. Indeed, the only difference will be, that not being secured on a wall, the level must be examined at each observation; whereas it appears, by a paper in the volume of the *Philosophical Transactions* for 1813, that the Greenwich instrument is so securely fixed, as to need neither level nor plumbline. It ought also to be remarked, that the small instrument has an advantage, which the mural circle does not possess, of having its divided surface turned either to the east or west, so as to give either zenith distances or polar distances in the manner which we shall now describe.

To illustrate the method which we propose to recommend, we shall take such a case as is most likely to occur to an ingenious astronomer who may possess such an instrument, and be inclined to avail himself of the powers it possesses. We shall suppose his object is to determine the north polar distance, or declination of a certain number of stars, if the result is intended to be of public utility; but few stars should be chosen, and those should be selected, whose places there is reason to suppose may not be accurately known; or the observer may attempt a series of circumpolar stars, with a view to determine the quantity of refraction best adapted to his own observatory. Perhaps it may admit of doubt, whether so small an instrument can be sufficiently accurate for so nice a purpose; but the method of observation is in each case the same. First, If zenith distances be required, (the co.latitude of the place being supposed known by previous observations of the pole star taken by repetition,) the method of proceeding is as follows: Clamp the back telescope firmly in any position, and observe a series of stars one night with the face of the instrument towards the east, observe the same series the next night with the face of the instrument towards the west, repeat this operation alternately, till a considerable number of observations are obtained, the means of the opposite readings will be the required zenith distances subject to the error of division; and as each star will have been observed on eight different arcs, this error will certainly be extremely small. To reduce it, however, to within still narrower limits, let the level be again moved to some new position, and another series be observed, the mean of the two will now approach nearer the truth, and this process of continually changing the telescope with its level should be persevered in, till satisfactory results are obtained. The principal error to be apprehended, is from the alteration which the bubble of the level may be liable to from change of temperature. Perhaps a judicious adaptation of a plumbline might for this reason be a great improvement to this instrument. If the pole star be observed both below and above the pole in every series, then the position of the polar point may be found, and the north polar distances will in that case be obtained by direct measurement from the pole. The reversion of the instrument, if this method be adopted, will have no other effect than to bring a new set of divisions into the series, and will be equivalent to a change of position of the level, and rather inferior in point of convenience. An intelligent astronomer will choose between these methods, and combine them according to circumstances, as it is almost impossible in practical astronomy to devise any general rule, that will not in many cases admit of considerable modification. Both these methods suppose, that the observer derives his results from his own observations alone; but we conceive that, for instruments of small dimensions, it would practically be much more advisable for an observer, to avail himself of the Catalogue of Stars given in the following page. Indeed, one of the principal intentions of this catalogue, is to afford to astronomers a certain number of standard stars, to enable them to determine the polar distances of other stars by comparison, in the same manner as Dr Maskelyne's Catalogue of the Right Ascensions is universally taken as a standard of comparison, when the right ascension of other celestial objects is required. We avail ourselves of this early opportunity of giving this catalogue to our readers. It is deduced from nearly two thousand observations, made with the most accurate instrument hitherto constructed.

If this method be adopted, the instrument should at first be so placed, as to mark nearly zero when the telescope points to the pole, a certain number of the Greenwich stars should be observed in each series, and from these standard stars the position of the instrument should be deduced, or, in other words, the error of collimation should be found.

With an instrument of such moderate dimensions, it may reasonably be expected, that different stars will give different results, therefore as many of these standard stars as possible should be observed every night, and the mean difference of the observed and computed place should be taken as the error of collimation, to be applied to the observations of the other stars, whose north polar distances it is the object of the observer to obtain. It is almost unnecessary to add, that if the sun, moon, or planets, make part of a series of observations, the same error of collimation is to be applied to them.

Having finished one series of results in the above position of the telescope, or rather level, it should be unclamped and changed to a new position, for instance, so as to mark 10° when the telescope points to the pole. In every observation now, the instrument will mark 10° more than the polar distance of the star, besides a new error of collimation, which is to be investigated by a comparison with the Greenwich Catalogue, the same as before.

By comparing these results with those obtained in the first position, the observer will be able to form some opinion of the degree of confidence to which his observations are entitled. He may now change the position of his instrument another 10°, and so proceed till he is satisfied of the accuracy of his catalogue. We are fully convinced, that, with the exception of Polaris and β Ursæ Minoris, a much more accurate catalogue may be made by this method than by the operation of repeating, which in fact does not appear to have ever been very successfully employed for stars south of the zenith, even by the French astronomers, notwithstanding their partiality to this instrument. The French instruments being very indifferently divided, the above method of observation would not suggest itself, because the error of a single observation would probably be very considerable; but in instruments of Mr Troughton's construction, it would rarely occur that the error of division would amount to 5″, the error of observation, bisection, level, &c. &c. must be common to every method that can be devised.

We shall now conclude this article with Mr Pond's Catalogue, referred to in the preceding page.

Mr Pond's Catalogue of the North Polar Distances of 44 of the principal Fixed Stars, deduced from 1452 Observations.

No.	Names of the Stars.		North Polar Distances beginning 1813.	Number of Observations.	Maximum of Error to which this Catalogue may probably be liable.

The stars α Aquilæ, α Arietis, and α Ophiuchi, are probably determined within a second of the truth; but Mr Pond met with some discordances in these stars which he does not comprehend. Future observations will shew, whether these are accidental, or arise from some periodical cause.

Those stars marked * were determined with the quadrant, its error having been ascertained by comparison with the circle, by other stars having nearly the same declination.

In the fourth column, Mr Pond has annexed the degree of uncertainty, or maximum of error, to which he conceives the results to be liable. These numbers not being derived from any strict mathematical process, must only be considered as indicating the opinion he has formed on the subject. When the observations themselves are published, we shall have an opportunity of stating at length the grounds of this opinion.

We are sorry that it is not in our power at present to communicate to our readers a complete account of Mr Pond's new method of determining the position of an instrument by means of the preceding Catalogue of Stars; but as that distinguished astronomer is at present engaged in drawing up a paper on this subject for the Royal Society, we shall be able to give a full account of it in another part of our work. It completely supersedes every other method, and renders the cumbersome apparatus of levels and plumblines completely unnecessary in fixed observatories.

Circle, Circuits.

CIRCLE, among the many fanciful analogies, which have been drawn by the ancients and moderns from the circle, or from lines drawn in and about it, it may be right here to mention the application of it to *music*, by the late Mr Harrison, the time-piece maker, who adopted a scale of temperament, wherein the major third has the same ratio to the octave, as the diameter of a circle has to its circumference; in which case $\text{III} = 194.77767\,\Sigma + 4f + 17m$, in Mr Farey's notation, or $\text{III} - 2\tfrac{1}{9}\Sigma$ very nearly. See HARRISON's *Temperament* of the Musical Scale. (ε)

CIRCLE. See GEOMETRY.

CIRCUITS, in law, are the journeys or rounds made by the supreme judges twice a year, for distributing justice in the different counties of the kingdom. In England, the circuits take place in the respective vacations after Hilary and Trinity terms; and the counties of that part of the kingdom, are distributed into six districts or circuits, viz. 1st, The *Midland* circuit; containing the counties of Northampton, Rutland, Lincoln, Nottingham, Derby, Leicester, and Warwick.—2d, *Norfolk;* containing Bucks, Bedford, Huntingdon, Cambridge, Norfolk, and Suffolk.—3d, *Home*; Hertford, Essex, Kent, Sussex, and Surrey.—4th, *Oxford;* Berks, Oxford, Hereford, Salop, Gloucester, Monmouth, Stafford, and Worcester.—5th, *Western;* Southampton, Wilts, Dorset, Cornwall, Devon, and Somerset.—And 6th, The *Northern;* containing York, Durham, Northumberland, Cumberland, Westmoreland, and Lancashire. Wales is divided into two circuits, south and north.

Scotland is distributed into three circuits—the *Northern*, comprehending the counties of Inverness, Ross, Elgin, Caithness, Sutherland, Cromarty, Nairn, Aberdeen, Banff, Kinkardine, Perth, Forfar, Fife, and the stewartries of Orkney and Zetland;—the *Southern*, comprehending Roxburgh, Berwick, Selkirk, Peebles, Dumfries, Ayr, Wigton, and the stewarty of Kirkudbright;—and the *Western*, comprehending Stirling, Clackmannan, Kinross, Lanark, Dumbarton, Renfrew, Argyle, and Bute. The periods, at which the Scotch judges perform their journeys, are some time in the course of the spring and autumn vacations of the court of session. See ASSIZES.

Circular ‖ Circumcision.

CIRCULAR PARTS. See TRIGONOMETRY.

CIRCULATION OF THE BLOOD. See ANATOMY, vol. i. p. 807, vol. ii. p. 18, and PHYSIOLOGY.

CIRCUMCISION, denotes the practice of cutting off the *preputium* or foreskin of the penis.

This practice was adopted universally among the Jews, and was also introduced partially, if not universally, among some other nations. The sacred scriptures carry the antiquity of this practice much farther back than any other writings. It is first mentioned in the 17th chap. of Genesis, and is stated as the sign or symbol of the covenant which God made with Abraham. *This is my covenant which ye shall keep between me and you, and thy seed after thee; every man-child among you shall be circumcised. And ye shall circumcise the flesh of your foreskin; and it shall be a token of the covenant betwixt me and you; and he that is eight days old shall be circumcised.*

Among the later Jews the ceremony was performed with much solemnity, in the synagogue, on the eighth day, as God had appointed. Two seats with silk cushions were placed, the one for the god-father, who was to hold the child, the other for Elias, who was supposed to be present at the ceremony. The child was brought to the door of the synagogue by the god-mother accompanied with other females, none of whom were permitted to enter. The godfather then seating himself in the chair which had been provided for him, held the child whilst the operator cut off the foreskin with a knife, a razor, or a sharp stone: a little styptic powder was applied to stop the bleeding, and the ceremony concluded with prayers and hymns.

It is not thought necessary to say more respecting the object of circumcision, as it is plainly stated in scripture to be a token of the covenant between God and the family of Abraham: and the propriety of the token may be inferred from this, that they who bore such an indelible mark of their affiliation to God, would be continually reminded of their allegiance, and excited to preserve inviolate that solemn covenant, whose external sign they never could disavow. But Jewish writers have endeavoured to extract several mystical meanings from the rite of circumcision, besides its avowed and obvious use, as the visible sign of a covenant. Philo says, that it represented the necessity of retrenching sensual enjoyments, and of keeping in proper subjection all those lusts, and passions, which war against the soul. This idea is countenanced by the scriptures; "The Lord thy God," says Moses, "*will circumcise thy heart* and the heart of thy seed to love the Lord thy God." "The house of Israel," says Jeremiah, "is *uncircumcised in heart*." Some authors have even maintained, that circumcision was not merely calculated to convey this typical, or figurative meaning, but had a physical influence in producing continence and purity.

As one great end of circumcision was to distinguish the Israelites from the surrounding heathen nations, they seem to have thought it allowable to omit the ceremony, when there was no danger of being confounded with their idolatrous neighbours. Hence they neglected circumcision during the time of their sojourning in the wilderness: after they had passed Jordan, Joshua circumcised all the survivors of those who had been born in the wilderness. Moses also neglected to circumcise his son in the land of Midian, which gave rise to a curious incident when he was returning with his wife and family, into Egypt. It is said that the angel of the Lord met him and sought to kill him. "*Then Zipporah took a sharp stone, and cut off the foreskin of her son, and cast it at his feet, and said, surely a bloody husband thou art to me: So he let him go; then she said, a bloody husband thou art because of the circumcision,*" Exod. iv. 25, 26. We quote this passage because it seems to be little understood, and also because it seems to point out a peculiarity attending the rite of circumcision. It is generally supposed that the words of Zipporah are addressed to her husband, by way of reproach; and that she speaks contemptuously of the circumcision. There is no ground for this opinion, but the mistranslation in our version. Zipporah, as being a Midianitess, and of course a descendant of Abraham by Keturah, could not be unacquainted with circumcision, which was observed by all the descendants of the patriarch: and the readiness with which she performed the operation, is a proof that she was no stranger to the practice. The whole difficulty has arisen from translating the word *chatan, a husband,* which never in Scripture has that signification, but means a father-in-law or a son-in-law, or a bridegroom in *the day of his espousals.* Hence the learned Joseph Mede supposes the words of Zipporah to be certain *verba solemnia* addressed to her child, intimating that she had espoused him unto God, by a covenant of blood: and this opinion is confirmed by the words of Aben Ezra on this place; *Mos mulierum vocare filium cum circumcisus est* חתן (*chatan*). See Mede's *Works, Castell. Lexic. Heptaglot.* and *Parkhurst*, who supposes the words addressed to the angel with the same figurative meaning.

It is now necessary to attend to the history of circumcision in different nations; for we find this singular rite observed, not only by the Jews, but by the Egyptians, the Ethiopians, the Arabians, the Phenicians, the Colchians; and we find it existing at this day among many people, whose connection cannot now be traced with any of these nations. Herodotus in his *Euterpe* wishes to ascribe the origin of this practice, as the Greeks did of every thing that bore the marks of great antiquity, to the Egyptians. His words are, Μουνοι παντων Κολχοι και Αιγυπτιοι, &c. "The Colchians and Egyptians are the only people who have practised circumcision from the remotest antiquity: for the Phenicians and Syrians in Palestine, (the Jews) confess that they borrowed this practice from the Egyptians. These are the only people who circumcise, and they seem in this to imitate the Egyptians: but I am not sure whether the Egyptians communicated this practice to the Ethiopians, or the Ethiopians to the Egyptians."

There is considerable confusion, as well as misrepresentation, in this passage: in the outset the historian ascribes the origin of the practice to the Colchians and Egyptians, but concludes with saying that he was not sure but the Egyptians might have learned it from the Ethiopians. The account of his testimony, respecting the origin of circumcision, is evidently this, that he knew nothing at all about the matter. His attestation, however, to the existence of the practice among the people whom he has specified, is entitled to attention, the more so, as it has misled several authors, and induced them to ascribe the origin of circumcision to the Egyptians. This opinion was adopted by Celsus and Julian among the ancients; and has been favoured among the moderns by Sir John Marsham, Spencer, and Le Clerc.

In the first place, Origen tells us expressly, that the practice was not general among the Egyptians, but was observed only by their geometricians, astronomers, and diviners. This affords a strong presumption that they borrowed the practice from Moses, whose power, as a worker of miracles, they had so often felt and confessed. The mathematicians, and men of science among the Egyptians, were all jugglers, and pretenders to miracles, and prophecy; and as they alone practised circumcision, what can be more natural than to suppose, that they adopted it in imitation of Moses, whom they could not but regard as an *Archimagus*, or master in the art which they professed.

But farther, the Scriptures afford strong reasons for believing that circumcision, at an early period, was little if at all known among the Egyptians. When Pharaoh's daughter saw Moses, she said, *this is one of the Hebrew children*, and it is thought that she discovered this, by the distinctive mark of circumcision, which immediately ascertained his origin, as the rite was then not practised among the Egyptians. In the days of Ezekiel, it is evident that Egypt was ranked with the uncircumcised nations, for it is said that it should lie *uncircumcised*, slain with the sword, along with Ashur, Elam, Meshech, and Tubal, chap. xxxii. It is very evident then, that circumcision was never generally practised among the Egyptians; that it was adopted at an early period by particular classes among them is not denied: but we have not the shadow of evidence that its antiquity among them approaches any thing near to the time of Abraham. The residence of a circumcised people among the Egyptians for four hundred years, may easily account for the origin of the practice; especially as the person who first introduced them into the country, was celebrated for his wisdom, as well as his power; and he who led them out of Egypt, became formidable by the tremendous miracles which he performed.

Let us then compare Herodotus with Moses, (and we shall claim for the latter only the privilege of an ordinary historian), and see whose account is most entitled to credit. Herodotus conjectures that circumcision had its origin among the Egyptians; Moses, who wrote about 1000 years before him, affirms that it originated with Abraham by the express command of God. Nobody can doubt that circumcision was practised by the Israelites at the time when Moses wrote, otherwise he never could have referred to it as an ancient practice: and would it not have been a most glaring absurdity, to state it as a distinction, as a token of God's covenant with the seed of Abraham, and as a mark of his peculiar people, had it been at that time generally practised among the Egyptians? In short, we have every evidence which the nature of the subject can afford, or which any reasonable person could demand, that the Israelites did not borrow circumcision from the Egyptians. Shall we affirm, then, that the Egyptians received it from the Israelites? We have stated reasons which seem to render this probable: but we think it still more probable, that they received it from some of the other descendants of Abraham. In this view of the subject, there is much probability in the conjecture of Herodotus, that the Egyptians might borrow the practice from the Ethiopians, meaning thereby the Arabians, for it is certain that Arabia is often called Ethiopia by the ancients; and the confusion was still more increased by this circumstance, that the Ethiopians of Africa, in all probability, came from Arabia, so that writers were induced to give the same names to countries which they found possessed by the same people.

Now, there is no doubt whatever that all the Arabians were circumcised, and that too, long anterior to the time of Moses: and the reason is obvious; they were the lineal descendants of Ishmael the son of Abraham, and, like the founder of their nation, were circumcised, not on the eighth day, but in the thirteenth year of their age; that being the age of Ishmael when God commanded Abraham to circumcise his family. Here, then, we have brought the Egyptians fairly within the contagion of the practice. And if it should be suspected, that they would not willingly borrow this custom from nations inferior to themselves in point of antiquity and refinement, we are not without grounds for supposing that it was imposed by force. Josephus, *contra Apion.* quotes a long passage from Manetho, an Egyptian author, who says, that a great part of Egypt was overrun by a race from Arabia whom he calls *royal shepherds,* and that they held the country in subjection for many years. If these conquerors were Arabians, then they were Ishmaelites who circumcised, and, like all sects, would probably have a desire to proselytize.

We would not venture to pronounce which of the circumstances we have mentioned, introduced the partial use of circumcision among the Egyptians; for it never appears to have been general; probably they might all conspire in producing this effect. We have shewn, however, from the most authentic documents, that circumcision was practised by the descendants of Abraham, at a time when the history of Egypt and of Greece was lost in fable. We have shewn also, that the Egyptians were frequently brought in contact with these people, and various reasons, besides those which have been mentioned, might be assigned for their adopting this practice.

But how shall we account for its introduction among other nations? From whom did the Phenicians receive it? If it ever was adopted by the Phenicians, properly so called, it may be easily accounted for by their vicinity to Palestine. But there is a strong probability that the Phenicians of Herodotus actually mean the Samaritans, their immediate neighbours, who were composed of the ten revolted tribes of Israel, and of course were all circumcised.

A long story is given, on the very questionable authority of Sanchoniatho, of circumcision being introduced into Phenicia by Ilus or Cronus. Sir John Marsham insists that this was no other than Noah, and that therefore circumcision must have been practised long before the time of Abraham; Shuckford maintains, with more probability, that this Ilus or Cronus, was Abraham himself, especially as it is said that this founder of the Phenician dynasty sacrificed his only son, and that this was the origin of human sacrifices among the Phenicians. But we should reckon it a waste of time to dwell on such a dubious argument. They who wish for farther information on this part of the subject may consult Shuckford's *Connect.* vol. 1. p. 326.

But circumcision was also practised by the Colchians; and it is not so easy to trace the manner of its introduction among this people. Grotius supposes, and the opinion is not improbable, that the Colchians, and some of the neighbouring nations, were part of the ten tribes who were carried captive by Shalmanezer. It is very evident that there was at that time a deficiency in the population of various parts of the Babylonian empire, and its monarchs swept away whole nations to supply the defect. The ten tribes never returned from their captivity, and evident traces of them are to be found at this day, in various places of that vast extent of territory, which was subject to the kings of Babylon: and this is a probable way of accounting for the existence of circumcision, among many modern nations, whose history is lost, and who exhibit no other marks of their origin. Grotius supports his opinion respecting the Colchians, and some of the neighbouring nations of Thrace, by quoting the Scholiast on Aristophanes; his words are, "*Colchi et eorum vicini ex decem sunt tribubus, quas transtulit Salmanasar. Inde et in Thraciam quidam venere. Scoliastes ad Aristophanes Acharnenses;* Οδομαντων εθνος Θρακικον, φασι δε αυτους Ιουδαιους ειναι. *Odomantum gens est Thracica: dicuntur autem esse Judæi.*"

We do not reckon it necessary to pursue this subject farther: the amount of our argument is this, that circumcision never was practised but by the descendants of Abraham, and those nations who learned it from them. It is universally practised at present by the Arabs, Moors, and Turks, who have derived it from the Saracens, the lineal descendants of Ishmael.

Some authors have endeavoured to assign physical reasons for the adoption of circumcision, such as cleanliness, convenience, &c. Were this argument admitted, it would destroy the notion of a positive appointment, and lead us to seek for the origin of the practice in causes common to many nations. But all the arguments which have been advanced in support of this opinion, appear equally futile and absurd. The practice was universally accounted disgraceful, especially by the Roman writers, and is the subject of many sarcasms; hence we have the *curtis Judæis*, and the *Judæus appella* of Horace, and the illiberal misrepresentation of Juvenal, in which he charges the Jews with want of common humanity, alleging it to be their practice.

Non monstrare vias, eadem nisi sacra colenti
Quæsitum ad fontem solos deducere verpos. Sat. 14. v. 104.

It is also evident that the operation was painful, and, in many cases, dangerous. The sons of Jacob employed it as a device to destroy the house of Shechem, by advising the young men to be circumcised, and then falling upon them before the wounds were healed, when they were unable to defend themselves. Tacitus's account of the origin of the practice, though imperfect, as was to be expected, is nevertheless correct so far as it goes. Speaking of the Jews, he says, " Genitalia circumcidere instituêre, *ut diversitate noscantur*." l. 5. *sub init.*

A very singular custom, however, is found to exist in modern times, in Egypt, Abyssinia, and several other countries, for which physical reasons are assigned, we mean the circumcision of females. The practice is different in different countries; those who wish to know the mode of performing the operation in Egypt, may find it detailed in Sonini's *Travels*, with a minuteness which we reckon improper for our work. A different mode is adopted in Abyssinia. Bruce calls it *exsection*, *quia fit exsectione clitoridis.* After Abyssinia was converted to Christianity, this practice was laid aside as a remnant of Paganism. It appears, however, that the men preferred the Pagan females who had undergone the operation, and serious apprehensions were entertained for the Christian faith. A representation was made to the court of Rome, and a skilful surgeon was sent into Abyssinia to examine into the merits of the case, and to report. In consequence of his representations, the Abyssinians were formally authorized to resume the practice, which continues among them to the present day. Our learned readers may see the reason of this practice in the following quotation from *Huet. not. in Origen.* " Circumcisio feminarum fit resectione clitoridis, quæ pars, in Australium præsertim mulieribus, ita excrescit, ut ferro sit coercenda. Ita tradunt medici insignes Paulus Ægineta, l. 5. c. 70. Aët. *tetrabib.* l. 4. *Serm.* p. 103. Quorum hic ita pergit: quapropter Egyptiis visum est, ut antequam exuberet pars illa corporis amputetur; tum præcipue cum virgines nubiles sint elocandæ. Porro hanc consuetudinem circumcidendarum mulierum hodieque retinere Egyptios, ferunt ii que regiones illas lustraverunt, ignemque ad compescendam hujus partis luxuriem adhibere scribit. Morem hunc servare feminas in Persia et Cophtas in Ethiopia, Christi licet nomen professas." (*g*)

CIRCUMFERENTOR is the name of a mathematical instrument for measuring angles by the magnetic needle. It is sometimes used in land-surveying, where an approximation to the truth only is required. It is now completely superseded by other instruments. See SURVEYING. (*w*)

CIRCUMVALLATION. See FORTIFICATION.

CIRCUS, an edifice in use among the Romans, for the exhibition of chariot races, and other games. The Circensian games appear to have been introduced at Rome from a very early period. They were probably borrowed from the Etruscans. They were established by Romulus almost in the beginning of his reign, and they continued to retain their popularity till the latest times of the empire. The circus at first was a wooden inclosure in which the spectators stood, a few seats only being placed for the persons of principal distinction. The most ancient permanent circus at Rome of which we have received any account, was that built by Tarquinius Priscus, in the valley Murcia, between the Aventine and the Palatine hills. This circus continued for a long time to be the only one in Rome. It obtained the name of the Circus Maximus, whether from its great superiority in size to those of a later date, from its being appropriated to the celebration of the greater games, or from its consecration to the great gods. It was enlarged by Julius Cæsar, and rebuilt and richly ornamented by Augustus. Tiberius, Caligula, Claudius, and Nero, all made additions to it. It was farther enlarged by Trajan. Constantine added to it some new porticos; and his son Constans ornamented it with the great obelisk at present at the Lateran. Dionysius of Halicarnassus states the dimensions of this circus, as it was left by Augustus, to have been, for the length 3½ stadia, the breadth 4 jugera, corresponding respectively to upwards of 3, and to about 1½ English furlongs. It could then contain about 150,000 persons. In consequence of the additions made to it previously to the time of the elder Pliny, it became capable of containing 260,000 spectators; and an inscription placed over the great gate subsequently to the alterations made upon it by Trajan, bore that that emperor had rendered it adequate to receiving the whole Roman people. Of this superb edifice there remain only some very indistinct traces, which are level with the ground. The remembrance of it, however, is still preserved by tradition; the site of the building, which is at present occupied by gardens, and the cemetery of the Jews, being distinguished at Rome by the appellation *Cerchi.*

The other circuses at Rome were numerous and considerable. The Flaminian circus was, according to Livy, founded by Flaminius, the unfortunate antagonist of Hannibal. This circus has been frequently noticed by ancient authors. Dion Cassius relates, that a chace of crocodiles was exhibited in it by Augustus, when 36 of these animals were killed. On the site of this building, there are now erected the church and convent of Santa Caterina de Funari, the two palaces of the dukes Mattei, with several other edifices. The only remains of this circus are ruins hid beneath the present pavement of the city, which is considerably raised in that part. Among these ruins, there still flows a considerable stream of water, which had been employed anciently for the supply of the circus.

A great part of what was the area of the Agonal circus is occupied by the modern Piazzi Navona. The houses situated at the northern extremity plainly follow, in their curved direction, the bend of the circular end of the ancient edifice.

One of the most remarkable of the Roman circuses was that which was begun by Caligula, and terminated by Nero. It appears to have been destroyed as early as the time of Constantine, since the former basilica of St Peter, founded by that prince, occupied the same situation as the present edifice, the right side of which rests upon the walls of the circus. The superb obelisk which at present ornaments St Peter's place belonged to that ancient edifice. From the exhibition given of the direction of the circus by Fontana, (*Il Tempo Vatic.* p. 245.) it seems to have been longer than the modern church, with the colonnade.

In some late excavations, there were discovered considerable remains of a circus, which, as it is supposed, was begun to be built by Nero in the gardens of his aunt Domitia, and was finished by Adrian. There were at the same time found several antique paintings.

A circus was built by Heliogabalus, on ground without the present Porta Maggiore. It was hence that the obelisk was taken, which is now erected in the interior garden of the Vatican.

There was a fine circus in the Sallustian gardens, which, it is said, might be filled with water for the exhibition of Naumachiæ.

There was also the circus of Flora, on the Quirinal, at which the exhibitions were given by the courtezans of Rome.

But of all the ancient Roman circuses, the one which preserves the most considerable traces of its ancient form, and by which, therefore, the modern inquirer might be best assisted in gaining some idea of these structures, is that which is situated beyond the Porta Capena, now Porta St Sebastiana, and of which the ruins have, by a uniform tradition, been designated as the remains of the circus of Caracalla.

In the plan of Rome by Panvinius, there are uncertain indications of some other circuses. There likewise still exist obscure traces of circuses in different parts of the world that had been anciently subject to the Roman empire;—at Tarragona, Merida, and Saguntum, now Murviedro, in Spain; at Nismes, at Milan, and Antioch. There remains also the ancient Hippodrome at Constantinople.

To maintain order in such a concourse of people as attended the exhibitions at the circuses, and to prevent any offence to the Roman pride, which was very jealous of any mixture of persons of different ranks, there were persons called designators, who were to assign to every one his place. With similar views, Tarquin divided his circus into 30 compartments, a number equal to that of the *curiæ* into which the people of Rome were at that time divided.

Though the circuses were primarily constructed for the exhibition of chariot races, they were used also occasionally for various other purposes. Indeed the Ludi circenses themselves, included several other exercises besides these. The magistrates also frequently held their assemblies in those edifices, and exercised those public functions, which, from the great multitudes of people attending, could not have been so well discharged in the temples and basilicas. Cicero informs us, that many harangues were pronounced in the Flaminian circus. Plutarch says, that Lucullus exhibited his triumph in this circus; and it was in the same place, that Augustus pronounced the funeral oration of Drusus. The Agnaninians having to assemble a general council, appointed it to be held in their circus, where they declared war against the Romans. The circuses were also a kind of public places, that were frequented by charlatans, diviners, and other people of that class. See Bianconi *Descrizione del Circo de Caracalla; Mosaique d'Italica.* (K)

CIRENCESTER, or CICESTER as it is pronounced, is a borough and market town of England, in the county of Gloucester: It is situated on the river Churn, on the borders of Wiltshire, at the meeting of the three Roman roads, Foss-way, Irmin-street, and the Icknield-way. The town consists of four principal streets, and seven of a smaller size, with several lanes, and occupies an area about two miles in circuit. A great part of the street which leads from Gloucester is a hollow way, where a small branch of the Churn passes, and again falls into its channel at the second bridge. The houses are chiefly built of stone, but the principal ones are generally detached from the rest. The parish church, which was built in the 15th century, is reckoned one of the finest edifices in the kingdom. The tower is 134 feet high, and has 12 bells. There were formerly other two towers, but they are both destroyed. It has five chapels of ease, of which St Mary's and St John's have stone roofs. The altar of St Mary's, which is not railed, has a stone pulpit, and is paved with black and white marble. The southern porch of St John's church, is a fine Gothic structure, and over the porch is the town hall. St Catherine's chapel, on the north side, is remarkable for the sculpture in the compartments of the roof; and in Trinity chapel, there are two monuments of marble in memory of Earl Bathurst, and his son the Lord Chancellor. The chief public institutions are three charity schools, and three hospitals. The principal manufactures of Cirencester, are one of curriers knives, another of fine cloth, and a small carpet manufactory, beside two breweries.

Cirencester was the *Corinium* of Ptolemy, and the *Durocornovium* of Antoninus. It had a castle in the time of the Romans, and the city was encircled with a wall and ditch. The castle was demolished in the reign of Henry III. A Roman mosaic pavement, and other ancient remains, have been found in the neighbourhood, and in 1723 a Roman building, supposed to be a hypocaust, was discovered. A piece of ground called the Querns, on the south-west of the town, is supposed to have been the site of a Roman theatre. The following is the state of the population for 1811:

Number of inhabited houses, ...	902
Number of families, ...	948
Families employed in trade, &c. . .	526
Males, ...	2030
Females, ...	2510
Total population, ...	4540

See Rudge's *Gloucestershire.* (*j*)

CIRKNITZ, LAKE OF, the *Lugea Palus* of Strabo, is a lake in Carniola, remarkable for several curious natural phenomena which it exhibits. It is situated about six miles from Laybach, and is surrounded on the north by rugged and frightful rocks. It is fully two leagues long from east to west, and one league in width from north to south. Its depth varies from 6 to 24 feet. There are three islands on the lake, the most considerable of which is called Vornek, which has sufficient surface for a village called Ottok, and a church. The other two islands are called the greater and the lesser Goritza. A tongue of land, called Dornoschek, stretches very far into the lake, and forms a peninsula which is separated from the isle of Vornek by a very narrow strait. Eight rivulets run into the lake, the largest of which are the Cirknitz and the Obiny. The former passes by a village of the same name, which is situated at half a league from its mouth. Without reckoning Cirknitz and Ottok, there are seven villages at a very short distance from the margin of the lake.

There is no exit for the waters of the lake, excepting by two openings at the level of the surface, called the greater and the lesser Karlouza, which are natural aqueducts formed out of the solid rock, and passing through the middle of the mountain to the opposite side of it, where they discharge the water at the grotto of St Cantianus. In addition to these two canals, there are no fewer than eighteen apertures at the bottom of the lake through which the waters often retire, and completely disappear.

When this singular phenomenon begins to take place, the waters first retire through the opening called *Kamine*, and disappear by degrees, till at the end of the fifth day the bottom of the lake appears around this opening. At the end of the next five days the bottom of the lake is seen around the opening called *Vodomo.* At the end of other five days, the pool *Reschetto* is evacuated; five days afterwards the *Koten* pool is emptied; and in five days more the *Levisde* is dried. In 25 days therefore the whole bed of the lake has become dry, the water having during that time been also carried off by the other thirteen apertures. The bottom of the lake is now cultivated, and sown.

Vegetation advances with extraordinary rapidity, and in the course of three months the peasants gather hay and millet.

It is generally about the end of four months that the waters begin to return. They rush through the different openings with great force, and in the space of about 24 hours, the lake is completely filled. Sometimes the lake has emptied itself thrice in one year; at other times years have elapsed without its having discharged its waters; but whenever the phenomenon does take place, the waters always return in less than four months. The phenomenon generally takes place about the end of June, or the beginning of July. In 1729, the waters were absorbed twice, once in summer, and a second time in winter.

A great variety of fish is found in this lake, such as pike, trout, tench, eels, carp, and perch. The pike sometimes weighs ten, twenty, and even forty pounds; and whenever the waters begin to retire, a bell is rung at Cirknitz, to give notice of the event to the neighbouring villages. Every thing is then prepared for fishing, and if the ebb happens in the night-time, the peasants fish even by candle light. Valvasor, in his description of Carniola, (*Die Ehre des Herzogthums Crain* &c. *durch*, W. Valvasor, 1689, 4 vols. folio,) informs us, that when the water is entirely run off into its subterraneous caverns, the peasants descend with lights into the cavity called *Ribescajama*, which is in a hard rock, three or four fathoms under ground, to a solid bottom, where the water is carried off through very small holes, as through a sieve; the fish being left behind in this natural net.

The fishing of the lake belongs to the six lordships of Hasberg, Steenberg, Auersperg, Lass, Schneeberg, and the convent of Sittich. Some pools are given to the fishermen for their trouble, and they sometimes sell their chance before they cast their nets. The lord of Steenberg once gave a fisherman 30 guilders for his chance in one pool, and the quantity of fish caught on this occasion amounted to fourteen cart loads.

The lake of Cirknitz stands higher than the country about Planina, which is on one side of it, and is a low valley with several cavities. The other side of the lake is surrounded with high mountains, so that the phenomenon of the lake might be explained on the principles of Hydrostatics. (*π*)

CITY (*civitas*), is defined by Coke, and after him by Blackstone, a town incorporated, which is or has been the see of a bishop; and though the bishopric be dissolved, as at Westminster, yet still it remains a city. Some, however, have disputed the accuracy of this characteristic difference between cities and other towns, the word *city* having, according to them, obtained in this island only since the conquest, though bishops, and their sees, were certainly known long before. It may be remarked also, as a very strong, or rather decisive authority in favour of this opinion, that Ingulph, in his History of the Abbey of Croyland, has related, that at the great council assembled in 1072, to settle the claim of precedence between the two English archbishops, it was decreed that bishops' sees should be transferred *from towns to cities*; and to this circumstance William of Malmsbury also refers; *concessum est*, says he, *episcopis de villis transire in civitates*. Yet though, originally, there thus appears to have been no necessary connection between cities and the sees of bishops, certain it is that for a long time the appellation has been confined to such towns only as either now are, or have been at some former period, honoured with that ecclesiastical distinction.

For a very distinct and probable account of the progress of cities, towns, &c. in wealth and consequence, see the *Wealth of Nations*, book 3. cap. 3. and Robertson's *Charles* V. vol. 1. See also Madox's *Firma Burgi*. and Brady's *Historical Treatise of Cities and Burghs*. (J. B.)

CIVIDAD RODRIGO, or *Rodericopolis*, a fortified town in the kingdom of Leon in Spain, was built in the 13th century, on the scite of the ancient *Mirobriga*. It is situated on the river Agueda, in a flat and good country, which produces grain of all kinds, wine, oil, honey, and almonds.

Cividad Rodrigo is well fortified, and has seven gates. The castle, though of a common construction, is very strong, and the ditch which surrounds the walls has been dug anew. The wall around the town is weak, but its platform forms an agreeable promenade. The streets are tolerably regular, and the public buildings are numerous. There is one cathedral, one collegiate church, six parish churches, five convents of monks, four of nuns, one seminary, and two hospitals. The cathedral, which was built in the time of Ferdinand II. of Leon, is of freestone, but is not finished. The church is Gothic, as well as the two parts of the cloister, but the other two parts are modern. There are three gates to the chapel, which is adorned with Corinthian columns. The finest piece of architecture is the chapel of Cerralvo, founded in 1588. Its form is square, and the body of it is in the form of a cross; the exterior decorations are of the Doric order, and the interior of the Ionic, with pilasters and a dome. There is nothing remarkable in any of the other churches, except that of the Augustines, which is well built, and adorned with five orders of architecture. In the church of St Francis in the Fauxburg, there is a handsome chapel, containing the tomb of a bishop of Zamara. The seminary was begun in 1765, and finished in 1769. Another building, larger than the first, and of the Doric order, was afterwards added, in which there was a church with vaulted roofs and a cupola. The principal altar is of stucco, and is of the Composite order. On the Plaza-Mayor there are three Roman columns on a triangular plinth, with two inscriptions on the cornice. The old Roman aqueduct is destroyed, but another has been erected for supplying the town with water.

There is in this town an agricultural society, who attend to the cultivation of the land, to the discovery of mines and quarries, and even to the instruction of youth. About ¾ of a league from the town is the beautiful convent of Norberlins. The cloister is magnificent, and charmingly situated near the river. Cividad Rodrigo was once famous for its manufactures of tapestries, embroideries, laces, and leather; but these are now gone, and there is only a small tannery and a manufactory for hard soap. Some of the inhabitants employ themselves in searching for grains of gold in the sands of the Agueda. The population of the town is 10,000. See Britain, Vol. IV. p. 723, 739. (*w*)

CIVIL ARCHITECTURE.

THIS term is meant to comprehend whatever relates to edifices appropriated to the purposes of civil life. These purposes vary with the progress of society, but we apprehend the whole may, with propriety, be classed under the heads of religion, legislation, public exercises and amusements, domestic life, and commerce. For the sake of distinctness, we shall divide the subject into the following parts, viz.

1. History of Architecture.
2. Principles of Architecture.
3. Practice of Architecture.

PART I. HISTORY OF ARCHITECTURE.

Of the origin of architecture.

RESPECTING the origin and early progress of architecture, it is in vain to expect much distinct historical evidence. Being indispensible not only for the comfort but the protection of mankind, the art of building must have been practised, and brought to a considerable degree of perfection, before lasting edifices were constructed; and it is only by means of works of this description, that we derive the earliest information respecting the art itself, and the other early acquirements of men. All the previous steps must consequently be unknown to us; but from observing the conduct of men now in a rude state, and, from the earliest authentic records, tracing the progress of others to civilization, wealth, and power, we are enabled to form a tolerably distinct notion of the early progress of architecture.

Buildings for domestic purposes being, from motives of œconomy, of slight construction, are, without much trouble or expence, varied, to suit the changes continually taking place in society. It is therefore to public buildings that we must have recourse, in order to trace the features of the art in remote ages.

In Egypt, Persia, and Hindostan, there are architectural works of great magnificence, whose æra of construction is by no means satisfactorily determined by historians. It is also uncertain in which of those countries architecture was first brought to this degree of perfection. Two very eminent authors (Sir William Jones and Dr Robertson,) after much investigation, infer, from the great and united efforts necessary to accomplish the architectural works found in Hindostan, and from the early and complete separation of the classes of society, that the eastern quarter of the world has a preferable claim to Egypt; and they also conceive, that Iran, or Persia, furnished to both the other countries the rudiments of knowledge. Others assert, that Hindostan is wholly indebted to Egypt, that this connection was early established through the means of colonies, who sought refuge in India from the tyranny of the shepherd kings, and that, after the expedition of Cambyses, the temples and tombs in Persia were constructed by Egyptian workmen.

The strong resemblance which subsists between many of the leading features in the magnificent tombs, temples, and palaces, in upper Egypt, and those at Salsette, Elephanta, and Vellore, and other parts of India, and also some of the splendid remains at Persepolis, is convincing evidence, that there has very early been a communication of architectural knowledge in those countries.

Simplicity of the Egyptian style.

If we were to form a judgment from the style of the architecture and workmanship of the several countries, the great simplicity of the Egyptian certainly establishes a strong claim to originality, and its perfect sameness is a strong evidence of its having been executed under the controul of one unvarying and despotic power,—a power which left no latitude for the exertion of individual originality of genius, and which was itself restricted by modes too sacred to be departed from. A power of this description indicates a state, whose establishments had been of long duration, and whose wealth enabled it to appropriate a large portion of unproductive labour. But the direction of this could not have been in the hands of despotic sovereigns, whose operations are too capricious and unsteady: it must have been a permanent establishment, which had also great influence in the state; and this, during the prosperity of the Thebaid, was precisely the case with the Egyptian priesthood.

Indian and Egyptian styles compared.

The Bramins of India formed a similar establishment, and the tombs and temples of that country are also of great magnitude and splendour; but in the Hindostan edifices, although many parts of the general arrangement and principal features resemble those of Egypt, yet simplicity has been more departed from, and circular outlines similar to those of pagodas have been introduced. The most splendid of the Indian edifices being wholly formed by excavation, may, most properly, be denominated sculptures; but even for this mode abundance of originals exist in Egypt. The numerous sculptured tombs adjacent to the principal cities in the Thebaid, are perfect examples as far as regards excavations within the natural rock, and the gigantic colossal statues are equally so as to isolated forms.

Persian and Egyptian styles compared.

The ancient Persian architecture, with the exception of some tombs, is composed of erections upon the surface of the ground. The pillars are more delicate, and the decorations of a less severe cast than those of Egypt.

In order to illustrate what has been advanced in this cursory view, we shall lay before the reader some details respecting the architecture of these three countries.

OF EGYPTIAN ARCHITECTURE.

Egyptian architecture.

Egypt being a country of small extent, and having been early and frequently conquered, the history of its ancient cities, palaces, and temples, was beyond the reach even of Herodotus. This parent of history only commences his account after the translation of the seat of empire to Memphis, and his personal intercourse with the country was not until a hundred years after its conquest by Cambyses. The origin and progress, therefore, of the powerful state which raised Thebes, and the other unrivalled edifices with which Upper Egypt was crowded, is to us totally unknown.

From the seat of empire having been first established at Thebes, and next at Memphis, we are led to conclude, that the original progress of colonisation was made in the same direction; but the periods or manner of this progress, as far as regards the cities of Upper Egypt, are involved in impenetrable obscurity. The forms of architecture and sculpture having been strictly determined, it is only from some shades of difference in the perfection of the workmanship of the latter, that we are led to conjecture that Apollinopolis, Tentyra, and Latopolis, are later works than the great edifices of Luxor and Karnac.

Tentyra, &c. later than Luxor, &c.

From the magnificent description of Thebes by Homer, we learn that it had risen to great importance previous to the Trojan war, or about 1200 years B. C. Memphis is said to have been built eight generations after Thebes, and Cambyses invaded Egypt 525 B. C.; so that for a period of 700 years, this country is known to have abounded in wealth and population; and when it is considered, that during this time the command of this wealth was in the hands of an able, artful priesthood, and unceasingly applied to the constructon of religious and royal edifices, we shall, after recollecting what was performed in Europe by similar means during a few centuries, be convinced, that the period before mentioned was alone quite sufficient for accomplishing even the justly celebrated works of the Thebaid.

Cambyses.

With the invasion of Cambyses terminated the splendour of Upper Egypt. He carried with him not only conquest but destruction. His warfare was not merely with the people, but with their palaces and religious structures. He carried off not only the spoils but the artists, leaving this once splendid valley a deplorable scene of ruins; and such is the fate of empires, that not more than two centuries had elapsed, when even these ruins suffered a further dilapidation from the destroyer of the Persepolitan palace of Cambyses. But notwithstanding all this, and also the repeated efforts of the more powerful Romans, and the natural waste of 3000 years, the magnificent and indestructible remains of Egyptian architecture at this day, exhibit a striking picture of that once powerful and learned people.

Alexander.

Structures of three different forms in Egypt.

Upper Egypt contains structures of three distinct forms. 1. The simple pyramid. 2. Apartments inclosed by sculptured walls with flat roofs, supported by rows of columns, and connected by open porticos. And, 3. Caverns, grottos, or tombs. We are here also without historical evidence, with regard to the priority or succession of these several modes. Some are of opinion, that caverns furnished first dwellings, and also places of worship, and that to these succeeded the simple pyramid; whilst others contend, that the colonnades were raised in imitation of groves of trees, in which were the earliest places of worship. The simplicity of the pyramid, and its having also been formed by the Spaniards in Mexico and Peru, would induce us to assign it a very early æra; but the Egyptian pyramids being situated at the northern extremity of the valley, in the neighbourhood of Memphis the *second capital*, we are at a loss to reconcile this circumstance with the previous reign of Thebes. If caverns have been the first habitations of the early inhabitants of Egypt, they must have occupied only what are now reckoned natural caves; for the excavations appropriated for tombs are arranged with great skill, and contain some of the most perfect sculptures and paintings. Indeed, from extensive ranges of ornamental tombs being constantly found adjacent to each great city, they evidently formed a part of the establishment, and they are also known to have enjoyed a very important place in the ancient Egyptian mythology.

Isle of Philee in the Nile.

The genius of Egypt appears with splendour at the very southern boundary of the empire; for the island of Philee, situated in the river Nile above the first cataract, (300 yards in length, and 140 in breadth,) has been wholly covered with temples. It was reckoned the sepulchre of Osiris, and deemed so sacred, that priests only were allowed to enter it. Some of the edifices appear very ancient, and others as if they had never been finished. In the latter, the sculpture is most perfect. Here the symbol of the hawk is very frequent.

Sepulchre of Osiris.

Isle of Elephanta.
Nilometer.

A little to the north of Philee is the isle of Elephanta, (2600 yards long, and 800 broad.) It was in a chamber in the middle of this island that the nilometer was placed. The temple has been dedicated to Horus, the Egyptian Apollo. The sculptured figures have more of the negro than in any other place. A granite statue of Osiris found here has never been finished. There is here a small peristyle temple apparently very ancient. Strabo found half the inhabitants of this island to be Ethiopians. Denon says, the temple was dedicated to the god Cneph, or the good genius, and that the symbols are serpents; and he thinks temples of this sort the most ancient. At Ombus, which is situated on the eastern side of the Nile, a temple has been dedicated to the crocodile.

Ombus.
Crocodile.

Apollinopolis.

Continuing down the valley, we arrive at Apollinopolis. It is situated on the western side of the Nile, in which is one of the finest, and, next to Thebes, the largest temples in Egypt. It was dedicated to Horus. The two moles which ornament the entrance are nearly in contact. The door is higher than in any other temple. It opens into a vast court, surrounded by columns, in form of a peristyle. The lodgings for the priests were behind the peristyle. The portico is formed of six columns in front, and three deep. The interior is arranged similar to Dendera, or Tentyra.

Edfou.

At Edfou, is a small temple to Typhon. There are here figures of the bad genius. The pictures represent the triumph of Hippopotamus.

Latopolis.
PLATE CXLVIII.

Still moving northward on the western side of the river, is Latopolis, which has a beautiful portico of six columns in front, and four deep; (see Plate CXLVIII.) the capitals differ, but are all elegant. The temple was dedicated to Jupiter Ammon. Here were found emblems of sacrifices of rams. There are four entire zodiacs at this place. On the other side of the river facing Latopolis, is a small temple, remarkable for having a gallery formed all round in the thickness of the wall.

Thebes.
Karnac.
PLATE CXLVIII.

At Thebes, there are magnificent ruins on both sides of the river; but Karnac and Luxor are on the eastern side, distant from each other about two miles. Karnac, (see Plate CXLVIII.) the greatest edifice in Egypt, Denon says, was dedicated to Priapus. The mole looks towards the Nile; it is 140 paces in length, and 25 in thickness: this leads to a court 110 paces in length, and the same in breadth. Two ranges of six columns, conducts to a portico composed of 136 columns. The two middle ranges of these are eleven feet diameter, the others are seven feet; the length of this vestibule is 78 paces, the breadth the same as the mole: it leads into a court, where there are four obelisks, and twelve colossal figures, each with a cross on its breast. Two other courts conduct to what is supposed the apartments of the kings; those of the king and queen are distinguished by doors of black granite. Adjacent to the great palace are many other buildings of great extent, connected with it by avenues of sphinxes, lions, and rams; some of the avenues extended towards Luxor, a distance of 1200 yards. The alley of lions is well preserved; they are 90 in number, and each is fifteen feet long, placed couchant upon a pedestal, about three feet in height, and ten feet asunder. Facing the moles, which condnct to the court of obelisks of the great

Avenues, sphinxes, lions.

Sculptures upon the exterior of the palaces.

palace, are two, and sometimes four colossal statues of sand stone, or granite; they are either seated, or in the act of marching, the arms hanging upon their sides, armed with a crooked poignard. The pictures which decorated the exterior of these different palaces, represent military subjects, sieges of cities, combats, offers of peace and submission by barbarians, triumphs of heroes who have conquered; the hero is represented by a young man of six feet high, mounted on a car precisely of the form used by the Greeks. The soldiers are scarcely one-fourth of this size. The enemies, put to the route, are men with beards, with a cap like the Spaniards. The Egyptians are armed with arrows; the barbarians with a buckler; they have also crooked sabres, lances, javelins, and a straight sword; the bridle of the horses resembles those still used in Arabia.

Plate CXLIX.

In approaching Luxor, (see Plate CXLIX.) the great objects crowded together at the entrance, are new to a European. In front of two great moles, 55 feet high, and distant only fourteen paces, stand two obelisks, 92 feet high, and between the obelisks and moles there are two colossal statues of black granite, each 38 feet high.

Memnonium or western bank.

Two great statues.

Plate CXLIX.

Tombs of the kings.

The first colonnade is ruined, the second still exists; it is formed of two ranges of eight columns; the total height being 56 feet, andthe diameter nine feet. At 28 paces to the right and left of the great colonnade, were two other ranges, 30 feet high, and four feet diameter. These structures, are on the eastern bank of the Nile. On the western side, on the scite of the Memnonium, is the immense statue of red granite, thrown down by Cambyses: its stature is 64 feet. Another smaller statue of rose granite is reckoned the finest in Egypt. Between the Memnonium and Medinet Abou, are two of the greatest statues in Egypt; their proportion is 55 feet; they are seated on pedestals, which are eleven feet high, (See *Collection of Fragments*, Plate CXLIX.) The space between Memnonium and Medinet Abou, which is about a mile and a quarter, is covered with fragments of colossus. Here appears to have been what Diodorus Siculus called the tomb of Osymandes. The palace of Medinet Abou has still preserved a peristyle, 55 paces long, and 65 in breadth, formed by four rows of columns, placed on the four sides of the court. The columns are 45 feet high, and seven feet diameter; the materials good, and the execution fine. In the hieroglyphics, the large figures have two inches relief, the smaller ones one inch. On the exterior of the palace wall, a bas relief represents a chase of lions, and an attempt at a descent by strangers, whose dress very much resembles that of Indians. The Egyptians oppose the descent by sea and land, and the barbarians are all routed. Under this picture is seen the march of troops heavily armed, and others armed lighter. The tombs of the kings are situated about 3¾ miles from the river, in a narrow valley, between the mountains of Lybia. In the time of Strabo, 17 of these tombs were found, and, including a grotto near the Memnonium, there is still the same number. They will be particularly described in their proper place.

Such are the outlines of the ancient and justly famed capital of Upper Egypt, as given by learned travellers; and more especially by Denon, and the French Commission of Arts, who examined it with zeal and care, under the protection of an armed force.

Tentyra.

Plate CXLIX.

Leaving Apollinopolis parva, and Coptos, on the eastern bank of the river, we find Tentyra, situated on the western bank. Here three temples have existed; the greatest, (see Plate CXLIX.) dedicated to Isis, is upon the same plan as that at Apollinopolis. The façade is 72 paces in breadth, and 145 in length. As the particulars will be detailed under the head of the Practice of Architecture, we shall here only remark, that there are two fine zodiacs to be seen; and that the sculpture of the human faces is much superior to that in any other place in Egypt. There was another smaller temple also dedicated to Isis, and a third to Typhon. The ruins of the city of Tentyra are said to cover about a square mile.

Panopolis, Lycopolis, Hermopolis.

Heliopolis.

In descending the valley, there are still the remains of Panopolis, Lycopolis, and Hermopolis, some of which yet exibited porticos, having eighteen columns; besides these, a multitude of fragments, in various other places, are evidence of temples or palaces having once existed. At Heliopolis, there remain only a solitary sphynx and an obelisk, to mark the scite of the city of the sun where Moses, Herodotus, and Plato were instructed in the learning of the Egyptians.

Five palaces and thirty-four temples in Upper Egypt.

Upon the whole, there are yet, it is said, in existence, in Upper Egypt, five palaces and 34 temples: the most ancient have been constructed chiefly with sand stone, and a few with calcareous stone. Granite was only used in obelisks and colossal statues.

Sanctuary of Minerva at Sais, a cube of sixty feet.

After the seat of empire was removed to Memphis, granite was made use of. The temple of Isis of Bahbeit was built of it. Immense masses were extracted and carried from Elephanta. The sanctuary of Minerva at Sais, and Latona at Butos, said to be cubes of sixty feet, were floated 600 miles, from Philee and Elephanta.

Memphis.

Pyramids.

The city of Memphis, the second capital of Egypt, is so completely destroyed, that its precise situation has not been clearly ascertained. It contained the celebrated temple of Phtha, (the vulcan of the Greeks); also one to Osiris, where the sacred ox was kept, and one to Serapis with an avenue of sphinxes at some distance. Strabo says, that there were many palaces situated along the side of a hill stretching down to lakes and groves, 40 stadia from the city; and it is known that they crossed lakes to convey their dead to the tombs, which were hewn out of the rocks. But the annihilation of the Memphian temples and palaces are compensated by the existence of the pyramids, which are alone sufficient to engage the attention of mankind. At a place called Sakkara, they are scattered over a space of twenty miles by seven. About thirty still exist, and there are traces of many more. The three largest are situated at Geez, and named from their founders Cheops, Chephren, and Mycerines. That of Cheops, which is the largest, is 448 feet in height, and 728 on each side of the base; Chephren 398 feet in height, 655 on each side of the base; and Mycerines 162 feet in height, and 280 on each side of the base.

The stone with which they are built is calcareous, fine grained, of a light grey colour, easily cut, light and porous, and readily imbibes water. By analysis it contains 95 carbonate of lime, 4 alumine, and 1 oxide of iron. The masonry is laid in mortar similar to that used in Europe.

The learned Mr Greaves, after much discussion, determines, from the best authorities, that the large pyramid was built 490 years before the first Olympiad, or about 3000 years ago.

Sphynx.

A little to the east of the second, or Chephren's pyramid, is the sphynx, cut out of the same sort of rock upon which the pyramids are built; the length is about 95 feet, and its height from the knees to the top of the head 38 feet.

It is still a doubt for what purposes these great edifices were constructed, whether for temples or sepulchres, or both. These points will be discussed at some length, and the particulars of their construction detailed under the articles TOMB and PYRAMID; but, in this ge-

Tombs.

neral historical sketch, we cannot avoid mentioning, that, from the peculiar notions the Egyptians held respecting the importance of preserving their bodies after death, they appear to have devoted much time and labour upon their sepulchres and tombs. In the whole of Upper Egypt, adjacent to each city, numerous tombs are always found excavated in the neighbouring mountains; the most extensive and highly ornamented are nearest to the base; those of smaller dimensions and less decorated occupy the middle; and the most rude and simple are situated in the upper parts. Those adjacent to Thebes, reckoned the tombs of the kings, are composed of extensive galleries, 12 feet broad and 20 high, with many lateral chambers. They are ornamented with pilasters, sculptures, stucco, and paintings; both ceilings and walls are covered with emblems of war, agriculture, and music; and, in some instances, with shapes of very elegant domestic utensils; and always representing offerings of bread, fruit, and liquors. The colours upon the ceilings are blue, and the figures yellow. We have, in Plate CXLIX. represented the entrance to those at Silsilis, situated between Edfou and Ombus.

Plate CXLIX.

Upper Egypt dilapidated by Cambyses,

and Alexander.

Alexandria.

Old Cairo.

From this sketch it will be evident, that the whole of Upper Egypt has been crowded with structures, composed in a style of architecture the most sublime and imposing which the world has ever beheld. It has already been mentioned, that Cambyses, from political jealousy or fanatical zeal, terminated his conquest of this country with a destruction bordering on frenzy; and also that Alexander, though a more liberal conqueror, after having, in a fit of intoxication, destroyed the Persepolitan Palace, contributed to the further dilapidation of the structures of the Thebaid, by using their materials in constructing the city of Alexandria. This city is one of the few instances, we distinctly know, where, under the direction of experience and intelligence, an entirely new situation has been chosen, and all the parts conducted according to a regular plan. Here the prince was the son of Philip and the pupil of Aristotle, and the architect (Dinocrates) was an enterprising Greek. The materials and mode of conveyance had all the perfection which the experience of 1000 years could afford; and the wealth and exertions not only of Egypt, but of all Asia, could be rendered subservient to this favourite project. The plan was extensive and magnificent; and a succession of wise and good princes rendered it, by means of Egyptian materials and Greek taste, the richest and most perfect city the world has beheld. Its chief features were two streets of great breadth, which crossed each other at right angles, and having all the smaller ones parallel to these. Besides all the private buildings, constructed with marble and porphyry, there was an admirable temple to Serapis, and another to Neptune; also a theatre, amphitheatre, gymnasium, and circus. The palace occupied one quarter of the city; but within its precincts were a museum for learned men, extensive groves, and a temple containing the sepulchre of Alexander. A mole of a mile in length extended from the Continent to the Isle of Pharos, where the famous lighthouse was constructed. This magnificent city maintained its importance for about 1000 years, under the Greek and Roman emperors. In the time of Augustus, it contained 300,000 free people, probably in all about 900,000; but, in the year 638, it was taken by the Saracen General Amrou, and, in 857, its walls were demolished. The foundation of Fostat, or Old Cairo, were laid by Amrou, where he pitched his tent previous to laying siege to Alexandria. Modern Cairo rose upon its ruins, and has been enriched with the spoils of Alexandria; from whence, it is said, 40,000 columns of granite, porphyry, and marble, have been brought, and erected in the mosques and private dwellings.

Of Indian Architecture.

Indian architecture.

Although what relates to India was anciently but very imperfectly known to the western world, yet such is the change in human affairs, and the eagerness with which every matter relating to India has of late been investigated, that we are now furnished with accounts fully as ample as those relating to Egypt or Persia. In the following brief relations we shall be guided by some excellent papers, by Sir William Jones and others, in the *Asiatic Researches;* Robertson's *Disquisitions respecting Ancient India;* the learned and laborious work of Maurice on *Indian Antiquities;* and the several other authorities quoted for particular descriptions.

Cities and palaces.

Oude.

Canouge.

Court removed to Delhi.

Canouge restored.

In India, the cities and palaces were on a scale with its great wealth and population. They were generally indebted for their origin to the favour of powerful princes, and successively became the centre of the riches and traffic of the East. In the historical poem, called the Mahabbarit, (or History of the Great War,) translated by Abul Fazel, the secretary or minister of the great Akbar, it is said, that Oude, the capital of a province of that name, to the north east of Bengal, was the first regular imperial city of Hindostan, and that it was built in the reign of Krishen, one of the most ancient rajahs. The Ayeen Akbery (vol. ii. p. 41.) represents Oude to have anciently been 148 coss (or about 259 miles) in length, and 36 coss (or about 63 miles) in breadth; but this bears more a resemblance to a province than a city. This city, says Sir W. Jones, "extended, if we may believe the Bramins, over a line of ten yojans, (or 40 miles.) It is supposed to have been the birth-place of Rama." According to the Mahabbarit, Oude continued the imperial city 1500 years, until about the year 1000 before the Christian æra, when a prince of the dynasty of the Surajas, who boasted their descent from the Sun, erected Canouge upon the banks of the Ganges, and made the circumference of its walls 50 coss, or about 87 miles. Strabo, from Megasthenes, who had seen Canouge, says it was situated as the confluence of another stream with the Ganges; that its form was quadrangular, the length 80 stadia, breadth 15, or, taking the mean stadium of the ancients, about 8 miles by 1½; that it had wooden fortifications, with turrets for archers to shoot from, and was surrounded by a vast ditch, (*Strabo*, lib. xv. p. 667.) Arrian calls it the greatest city amongst the Indians; he says, that it was situated at the junction of the Erannaboa with the Ganges: he gives the same dimensions as Strabo; and says, that there were 570 towers on the walls, and 65 gates. Diodorus Siculus, lib. xvii. p. 678, says, that when Alexander passed the Hyphasis, he was informed, that, on the banks of the Ganges, he would meet the most formidable sovereign of India, called Xambranes, king of the Gangarides, at the head of 20,000 horse, 200,000 foot, 2000 war chariots, and 4000 fighting elephants. The Mahabbarit states, that Sinkol, a native of Canouge, brought into the field, against Affrasiah, king of Persia, 4000 elephants, 100,000 horse, and 400,000 foot. But that after Delu had founded Delhi, and established his court there, Canouge declined, and was involved in civil discord;—still we learn from the same authority, that Sinsarchand, or Sandrocottus, the successor of Porus, restored Canouge to its ancient splendour; and that here, about the year 300 before Christ, he entertained the ambassadors from Seleucus, the successor of Alexander, and that Megasthenes was amongst the number. In the beginning of the 5th century, Ramdeo Rhator (or the Mahratta) entered Canouge in triumph, and reigned there 54 years. The last king under whom this city may be considered as the metropolis of a great empire was Maldeo, who, about the beginning of the 6th century, added Delhi to his dominions. At this time, Canouge was said to contain 30,000 shops, in which areca was sold. Although not the metropolis, it long after continued of great consequence. About the year 1000, when Sultan Mahmed invested it, it is represented as a city which, in strength, had no equal. It became an appendage to the empire established by Mahmed. *Ferishta*, vol. i. p. 27.

Major Rennel is of opinion that Canouge and Palibothra were the same. Others endeavour to prove the contrary; and that both may have existed at the same time capitals of the Prasii, as Delhi and Agra have done in later times.

Delhi founded by Delu, 300 B. C.;

The precise period of the origin of Delhi is not correctly ascertained: According to the Ferishta, it was founded by Delu, who usurped the throne about 300 years before Christ. The Ayeen Akbery fixes it about the commencement of this æra, and informs us, that twenty princes of the name of Bal, or Paul, followed in regular succession for 437 years; that the last of its native princes was Pithoura, when it was conquered by the Mahomedan slave Cattub, named by Herbelot, Cathbaddin Ibek, who made Delhi the capital of the vast empire he established in Hindostan; and that each successive monarch of the Mahomedan dynasty adorned it with splendid edifices, appropriated to the purposes of religion and commerce. At the invasion of Timur Bec, it had arrived at the highest distinction for commerce and wealth, being then the centre of the traffic carried on between Persia, Arabia, and China. Timur entered it on the 4th July 1399; and on the 13th of the same month, this celebrated city was destroyed. Sherifedden, the Persian historian, says, that Old Delhi was celebrated for a mosque and palace, built by an ancient Indian king, in which were 1000 marble columns. Under the dynasty which succeeded Timur, it recovered its original splendour, and was again ornamented with mosques, baths, caravanserahs, and sepulchres.

destroyed in 1399, by Timur.

Agra founded by Akbar.

Delhi restored;

The great Akbar, the glory of the Timur house, having fixed his residence at Agra, Delhi, of course, experienced a partial eclipse; but in 1647, according to Fraser, Ischaim Shah, the grandson of Akbar, restored Delhi under the name of Ischaimbad, where he built a magnificent palace, formed extensive gardens, and constructed a throne in the shape of a peacock, whose expanded tail was entirely composed of diamonds, and other precious stones. It continued the capital of Hindostan till 1738, when it was sacked by Nadir; and afterwards repeatedly by Ahmed Abdallah, from 1756 to 1760, when it was totally destroyed. During the reign of Aurenzebe, it was said to contain two millions of habitants:

totally destroyed 1760.

Lahore.

Lahore is situated to the north-west of Delhi, on the banks of the Rauvee, the ancient Hydraotes: it appears to have been the Bucephalus of Alexander. Jeipal, the rajah of Lahore, during the incursions of Subuitagi, and his son Mahmud, defended his possessions with great bravery; and so great were his riches, that, when taken prisoner, around his neck alone was suspended sixteen strings of jewels, each of which was valued at 180,000 rupees, and the whole at L. 320,000. Lahore continued to flourish under the sultan of Cosro, and was the imperial seat of Cuttub before he removed it to Delhi; even afterwards it remained the general storehouse for the traffic of Persia, Arabia, India, and China. It was restored by Homaion, who, amongst other magnificent buildings, erected a palace, which was completed by Ischaim Geer, the son of Akbar. This palace, according to Mr Finch, who visited it in 1609, had twelve gates, nine towards the landside, and three towards the river. He says, the rarities were too numerous and glorious to be represented in a description; that the mahls, courts, galleries, and rooms of state, were almost endless; and that, in the king's lodgings, the walls and cielings were overlaid with plates of gold. M. Bernier, who was in this city in the suit of Aurengzebe, speaks of this palace as a high and magnificent building, but then hastening to ruin.

Visited in 1609 by Mr Finch.

Agra

Agra, the Agara of Ptolemy, situated in 27° 15′ north latitude, on the bank of the Jumna, we have already observed, was raised to splendour by the great Acbar. He caused the earthen wall, by which the city had been inclosed by the Patan monarchs, to be taken away, and replaced by one of hewn stone, brought from the quarries of Fettipore. He collected the most skilful artificers from every part of his dominions; and the palace alone employed above 1000 workmen for twelve years. The castle was built in the form of a crescent, upon the banks of the Jumna; and in a line with it were ranged the palaces of the princes and great rajahs, intersected with canals and beautiful gardens. Acbar also erected many caravanserahs and mosques. He invited foreigners of all nations; he built them factories; and permitted to all the free use of their religion. It was soon crowded with Persian, Arabian, and Chinese merchants, besides those immediately from European settlements. But when Ischaim removed the imperial insignia and treasures to Delhi, and made it the residence of his court, Agra sunk rapidly to decay.

made a free city by Acbar.

These five imperial cities seem, with regard to extent, splendour, and wealth, to have exceeded the greatest cities of the western world: And, beside these, many others were almost of equal magnificence; for Chundery is said to have contained 384 markets, and 360 caravanserahs; and Ahmedabad was once so large as to require to be divided into 360 quarters. Maurice, *Ind. Antiq.* vol. i. pp. 118, 124.

These extensive and proud cities, were evidently the symbols of temporary policy and power, and have passed away, like so many splendid scenes on the great theatre of the East. From the particulars which will be detailed under the Practice of Architecture, we shall be able to form some notion of the eastern manner of building; but as the religion of India has been more permanent than their political relations, it is from the sacred edifices we are to trace most distinctly the characters of Indian architecture, and be enabled to judge how far they have any affinity with those of other nations. Of their large temples (pagodas) we find accounts of five different forms.

Temples in five different forms.

Pyramids.

1. Simple pyramids constructed of large stones, and diminished by regular recesses or steps, as at Deogur and Tanjore; the exterior rude, and the interior having only lights from without by a small entrance door; illuminated by a profusion of lamps, with the exception of a chamber in the middle, which has only a single lamp. Aquetil says, that to him one of the mountains of Canara seemed hewn to a point by human art.

Excavations.

2. The second kind were formed by excavations in the sides of rocky mountains. Abul Fazel (*Ayeen Akbery*, vol. ii. p. 208.) says, that, in the soobah of Cashmere, in the middle of the mountains, 12,000 recesses were cut out of the solid rock. From Captain Wilford's paper on Caucasus, inserted in the sixth volume of the *Asiatic Researches*, we learn, that an extensive branch

of the Caucasus was called by the Greeks Parapamis, obviously derived from Para Vami, the pure and excellent city of Vami, commonly called Bamiyan. It is situated on the road between Balkh and Cabul, and, like Thebes in Egypt, consists of vast numbers of apartments and recesses cut out of the rock; some of which, on account of their extraordinary dimensions, are supposed to be temples. There are also, at that place, two colossal statues, one of a man eighty ells high, and another of a woman fifty ells high, erect, and adhering to the mountain from which they are cut. At Salsette, Elephanta, and Vellore or Ellora, the excavations were not only extensive, but were divided into separate apartments, with regular ranges of sculptured pillars and entablatures, and the walls and ceilings covered with multitudes of figures of their genii, deutahs, men, and women; and various animals, such as elephants, horses, lions, &c. all of the most excellent workmanship. See Plate CLI. and CLII.

Plates CLI. and CLII.

Square or oblong courts.

3. A third set were composed of square or oblong courts of vast extent. The circumference of the outward wall of that in the island of Seringham, adjacent to Trichinopoly, is said to extend nearly four miles. The whole edifice consists of seven square inclosures, the walls being 350 feet distant from each other. In the innermost spacious square are the chapels. In the middle of each side of each inclosure wall there is a gateway under a lofty tower: That in the outward wall which faces the south, is ornamented with pillars of single stones, thirty-three feet long, and five diameter, (Voyages *de M. Sonnerat*, tom. i. p. 217; and Robertson's *India*, p. 268.) Tavernier describes the Pagoda of Santidas, in the Guzzerat, as consisting of three courts paved with marble, and surrounded with a portico supported by marble columns: the inside of roof and walls formed of mosaic work and agates, and all the portico covered with female figures cast in marble. Aurenzebe profaned this temple by killing a cow within its precincts, and converting it into a Turkish mosque. At Chittambrum, on the coast of Coromandel, there is only one court, 1332 feet in one direction, and 936 in another, with an entrance gateway under a pyramid 120 feet high, and the ornamental parts finished with great delicacy. John Call, *Phil. Trans.* vol. lxii. p. 354. Orme's *Hist.* vol. i. p. 178.

In the form of a cross.

4. A fourth sort, as Benares Pagoda, in the city of Casi, which from the earliest times was devoted to Indian religion and science. The temple is in the form of a cross, with a cupola terminated by a pyramid in the centre, and having also a tower at each extremity of the cross. From the gate of the Pagoda to the Ganges there is a flight of steps. *Tavernier*, tom. iv. p. 149. Rouen edit.

Circular.

5. A fifth are made in a circular form, as the celebrated pagoda of Juggernaut, which Hamilton compares to an immense butt, set on end. Juggernaut, only another name for the god Mahadeo, who is represented by the vast bull which juts out of the eastern aspect of the building. It is the seat of the arch-Bramin of all India, and its sacred domains are said to afford pasturage for 20,000 cows.

Bezoara or Buswara.

Besides these general terms, if our limits permited us to trace those interesting structures through the various districts of this extensive country, many different arrangements might be described; but, for the present, we must be satisfied with mentioning the pagoda of Bezoara, (or Buswara of Major Rennel) now a fort upon the Kistna river; it was not inclosed with walls, but erected upon 52 lofty columns with statues of Indian deities, standing between the columns. It was situated in the midst of an oblong court, round which there was a gallery raised on 66 pillars like a cloister. (*Voy. des Ind.* tom iii. p. 226. Rouen Ed. 1713.) Near this, on a hill ascended by 193 steps, was another pagoda of a quadrangular form, terminated by a cupola.

Temples placed on the banks of the Ganges, &c.

These temples were generally erected on the banks of the Ganges, Kistna, and other sacred rivers for ablution. Where there was no river, a tank or reservoir of a quadrangular form was constructed and lined with free-stone or marble, with steps descending into them. Crawford observed many 300 or 400 feet in breadth. (Crawford's *Sketches*, vol. i. p. 106.) At the entrance of the principal pagodas, there is a portico supported by rows of lofty columns, and ascended, as in the case of Tripetty, by more than 100 steps; under these porticos, and in the courts which generally inclose the buildings, multitudes attend at the rising of the sun, and having bathed and left their sandals at the border of the tank, impatiently await the unfolding of the gates by the ministring Bramin. *Thevenot.*

Sculptures.

We must reserve, until we come to treat of the Practice of Architecture, many particulars relative to those splendid edifices, which, with the Plates accompanying them, will afford a more distinct view of the nature of their arrangements and appropriations; but it will be proper in this place to notice some leading circumstances respecting the Indian sculptures, with a view to ascertain what affinity they had to those in Egypt.

Excavations in the Soubah of Cashmere.

Colossal statues.

Juggernaut black stone.

Two tygers.

From the Ayeen Akbery, and Captain Wilson's paper on Caucasus, we find, that in the Soubah of Cashmere, between Balkh and Cabul, in the numerous excavations, there are 700 places where the figure of a serpent is carved; and that near these excavations, there are sculptured in rock, on the side of the mountain, figures of 15, 50, and 80 ells high; that in the great temple of the Sun, which was near Juggernaut, and said, by the Ayeen Akbery, to have consumed, in the expence of building, the whole revenue of the Orissa for twelve years; that in front of the gate, there was a pillar of black stone, of an octagon form, 50 cubits high; that at the eastern gate, there were two elephants, each with a man on his trunk; at the western gate were figures of horsemen, completely armed; and at the northern gate two tygers, who had killed two elephants, and were sitting upon them. That in one extensive apartment, there is a large dome constructed of stone, upon which is carved the sun and stars, and round them a border of human figures. In the Pagoda at Juggernaut, Hamilton describes the idol as a huge black stone, of a pyramidal form; and there was a bull, representing the god Mahadeo, jutting from the wall of the eastern aspect. Tavernier observed a conspicuous idol of black stone in the temple of Benares; and that the statue of Creeshna, in his celebrated temple of Mathura, was of black marble. In the great Pagoda at Elephanta, the bust of the triple headed deity measures 15 feet from the base to the top of the cap, the face is five feet long, and it is 20 feet across the shoulders. Along the sides of the cavern are colossal statues, to the number of 40 or 50, from 12 to 15 feet high; some have a sort of helmet of a pyramidal form; others a crown with devices; others display bushy ringlets, some with curled, and others with flowing hair; many have four hands, some six; with sceptres, shields, weapons of war, and symbols of peace. At the west end of the Pagoda, there is a great dark recess, 20 feet square, totally destitute of ornaments, except the altar in the centre, and the gigantic figures which guard the several doors which lead into it. Niebuhr says, these figures are eight in number; they are naked, and 13½ feet high;

Colossal statues at Elephanta.

Salsette.

their heads, decorated like the other statues, have rich collars round their necks; and jewels of great size in their ears. In the before mentioned recess, the Lingam divinity is represented. The Pagoda at Salsette exceeds that at Elephanta; the two colossal statues immediately before the entrance of the grand temple are 27 feet high; they have caps and ear-rings. There are here two hundred figures of idols; 90 of which are in and about the great pagoda. In the interior spaces which recede from the apartments, the Lingam is represented. Many of the sculptures in these grand temples have reference to the astronomical, as well as mythological notions prevalent in India.

Vellore.
Plates CLI. and CLII.

At Vellore, Ellore, or Ellora, (Plates CLI. and CLII.) the sculptures, &c. are still more extraordinary; and all are dedicated to the Lingam or Mahdeu. The height of the grand pyramid is here 90 feet; the smaller ones 50 feet; the obelisks 38 feet. The elephants on each side of the court are larger than life; and there is an apartment for the Bull Nundee. See C. W. Malet's paper, *Asiatic Researches*, vol. vi. p. 383.

Eswara and Isi the same as Isis and Osiris.

Sir W. Jones (*As. Res.* vol. i. p. 253.) is of opinion, that the Eswara and Isi of the Hindoos, are the Isis and Osiris of Egypt. He says, that the word Misr, the native appellation of Egypt, is familiar in India; that Tirhoot was the country, asserted by a learned Bramin, to be that in which an Egyptian colony of priests have come from the Nile to the Ganges and Yamma (Jumna). And again, in his third annual discourse, the remains of architecture and sculpture in India, prove an early connection between this country and Africa, the pyramids of Egypt, the colossal statues of the Sphinx, and the Hermes Canis, which last bears a great resemblance to the Varahavatu, or the incarnation of Vishnu, indicate the style and mythology of the same indefatigable workmen, who formed the vast excavations of Canarah, the various temples and images of Buddah, and the idols which are continually dug up at Gaya.

Kempfer asserts, that the great Indian saint, Buddha, was a priest of Memphis, and having fled to India, introduced the worship of Apis. (Kempfer's *Hist. Japan.* vol. i. p. 38, ed. 1738.)

Athanasius Kircher is of opinion, that after Cambyses had murdered Apis, the most revered of the Egyptian deities, he committed wanton cruelties on the priests, and destroyed their magnificent temples, as related by Herodotus, that the priests flying into the neighbouring countries of Asia, propagated the superstitions of Egypt.

The lotus was anciently in Egypt, and still in India, held sacred. Herodotus calls it the lily of the Nile. The Egyptian priests had a sacred language, so have the Bramins. The Egyptians, according to Diodorus Siculus were divided into five tribes, of which the first was sacerdotal. The Indians are separated into four, besides an inferior one, named Buzzer Sunker.

Father Loubere, who went ambassador from the king of France to the king of Siam, in 1687, thinks the superstition of Boodh no other than the Sommonacodom, or stone deity of the Siamese, originally from Egypt. He says, that their astronomers, have fixed the death of Sommonacodom to the year B. C. 545, and that it was then their first grand astronomical epochs commenced. Now, by Usher, Cambyses invaded Egypt in 525. Loubere adds, that the Siamese priests live in convents, which consist of many cells ranged within a large inclosure; that in the middle of the inclosure stands the temple; that pyramids stand near to and quite round the temple, all within four walls. See Loubere's *Hist. of Siam,* in Harris's *Coll. of Voy.* vol. ii. p. 482.

Sir W. Jones thinks, that the great statue of Narayen, or the Spirit of God, who, at the beginning, floated on the waters, as that statue is now to be seen in the great reservoir of Catmander, the capital of Nipaul, is the same as the Cneph of Egypt, under a different appellation; both statues are made of blue marble. See *Asiatic Researches*, vol. i. p. 261.

Mr Call has published a drawing of the signs of the zodiac, which he found in the ceiling of a choultry at Verdapettah, in the Madurah country, viz. Brahma painted in pagodas, in the act of creation, floating over the watery abyss, reclining upon the expanded leaf of lotus, Osiris found in the same attitude, recumbent on the same plant, in the Egyptian monuments. Maurice, vol. ii. p. 394.

Of Persian Architecture.

Persian architecture.

The south western districts of Asia, although the centre from whence, we have reason to think, mankind originally spread in all directions, has undergone such frequent and complete changes, that we have scarcely any vestiges of its very ancient edifices left, and even the descriptions of the earliest historians convey but imperfect ideas of their magnitude or forms; the reason of this will be evident, from considering that the dominion has been successively in the hands of the Assyrians, Medes, Persians, Greeks, Romans, Saracens, and Turks.

General remarks.

Although there may be reason to suspect some exaggeration in the accounts transmitted by Herodotus and others, it is clear they were the results of the enquiries of curious and able men; they at least prove, that the magnitude of the cities, palaces, and temples of Assyria and Chaldea, must have been very great; and when we consider the population and riches of the empires of which these cities were the capitals, and that to their decoration every despotic monarch would apply the whole resources of his empire, we should hesitate in assigning the limits of their operations, particularly when it is considered, that although despotism cannot create genius, or oblige it in a short period to produce fine architecture, sculpture, and painting, yet when magnitude alone is concerned, simple manual labour to almost any extent was perfectly within its power. Those who will take the trouble of acquiring a distinct knowledge of what has been performed during the last 50 years, in extending towns, constructing harbours, navigable canals, roads, and bridges, within the island of Great Britain alone, will not be astonished by the accounts given of the vast cities of the east.

Babylon and Nineveh appear both to have existed at the same time, and to have been nearly of the same magnitude, viz. from 48 to 60 miles in circumference.

Babylon.

Babylon was situated in 32° 34′ N. Latitude, and 44° 12′ 30″ E. Longitude, in the extensive and rich plain of Shinar, at the top of the Delta, formed by the Euphrates and the Tigris. Its original founder is said to have been Nimrod, 2000 years B. C. but it was rebuilt by the celebrated Assyrian queen Semiramis, 1200 B. C. and enlarged and perfected by Nebuchadnezzar, about 600 B. C. It was divided by the Euphrates passing through it from north to south, the old city being on the east, and the new on the west side of the river, both together forming a square 15 miles on each side. It was divided by 25 streets 150 feet broad, running in each direction, and crossing at eight angles, besides streets of 200 feet in breadth, passing along the inside of the walls; the whole space was thus divided into 676 squares, along which the houses were built at some distance from each other. The intermediate spaces were occupied by gar-

dens and groves of trees. The walls which encompassed the city are said by Herodotus to have been 385 feet high, and 87 in thickness; they were built of brick, laid in a mortar made of bitumen; they were surrounded by a ditch, from which the bricks had been made. Darius Hystaspes afterwards reduced them to 50 cubits in height. There were 25 gates in each side, opposite to the streets; and upon the walls, between the gates, were lofty towers. The sides of the river were faced with brick work as quays; and in the middle of the city was a bridge. This bridge was constructed of pillars set at 11 feet distance, and covered with stones laid horizontally; the roadway was 30 feet wide. Above the city two canals were cut from the Euphrates to convey the flood water to the Tigris, and to the west was an artificial lake 40 miles square, which received the water of the river while the quays were constructing; the lake was afterwards used for watering lands. At each end of the bridge was a palace; the old one at the east end was surrounded by three walls placed at a considerable distance from each other, the whole being 30 furlongs in circuit. The new one, by Nebuchadnezzar, was on the western side, and is said to have been eight miles in circuit, but this no doubt also included the royal gardens and parks. The walls were embellished with sculpture, particularly one piece representing Queen Semiramis on horseback, throwing her javelin at a leopard, while her husband Ninus is piercing a lion. The temple of Belus occupied one square. Near the old palace, in the middle, stood the ancient tower, the base of which was about 600 feet on each side, it consisted of eight towers placed on each other, and each 75 feet high: it diminished as it rose, and was ascended by means of an inclined plane, which passed eight times round the tower. In these towers were apartments supported by pillars: these were the temples, the uppermost being the most sacred. The top is said to have been an observatory. Nebuchadnezzar surround- this tower with buildings, so as to occupy a square of two furlongs on the side, and surrounded by a wall two miles and a half in circuit. There were several brazen gates, and many idols of gold, especially one of Belus 30 feet high, placed on a pedestal 50 feet high.

Alexander.

Inhabitants removed to people Seleucia.

Cyrus, about 540 B. C. took Babylon, by diverting the water of the Euphrates, and entering by the dry channel into the city. Susa being his capital, Babylon rapidly declined in grandeur; having revolted, it was again taken by a vile stratagem by Darius Hystaspes, who demolished its gates, and reduced the walls. His successor Xerxes, in 478 B. C. when returning from his inglorious expedition to Greece, plundered and demolished the tower of Belus. The enterprising Alexander, in 324 B. C. meant to have rebuilt it, and actually employed workmen to clear out the ruins, but his premature death interfered with this and many other splendid projects. In 294 B. C. it was almost exhausted of its inhabitants by Seleucus Nicanor to people his new city Seleucia. It suffered greatly by the neglect of the Parthian princes before the Christian æra; and in the 4th century, Jerome informs us, that, "its walls were employed by the Persian princes as an enclosure for wild beasts, preserved there for the chase."

Such has been the rise, progress, and termination of this singular city, where architecture was practised on a truly gigantic scale. Had the materials employed been granite, porphyry, or marble, instead of bricks, we should still, doubtless, with regard to mass, have had fragments worthy to be compared with those of Upper Egypt; but as it is, we are to remember, that the latter part of the period we have been contemplating, is distant 2400 years, and that the constructing and ornamenting of Asiatic cities, was governed by the vanity and caprice of despotic sovereigns, instead of the unvarying pursuits of a permanent independent priesthood.

Nineveh.

From the best authorities, it appears, that Nineveh resembled Babylon in form, extent, and population. Diodorus Siculus says it was 480 stadia in circuit, that its walls were 200 feet high, and that there were 1500 towers. Strabo admits, that it was larger than Babylon. It was taken by Arbaces and Belesis, 747 B. C.; and again by Astyages, 626 B. C. when it was totally ruined.

Susa.

The next imperial cities were Susa and Ecbatana. Susa was built or restored by Darius Hystaspes; it was an oblong of 120 stadia in circuit, and situated upon the river Uhlai, or Cutæus.

Ecbatana.

Ecbatana was built by Deioces, king of the Medes; it stood upon a gentle declivity, 12 stadia from the Mount Orontes; its circuit was 150 stadia; it was unwalled, but had a strong citadel or palace, encompassed by seven walls, each distinguished by a separate colour, and rising gradually above each other. Herodotus says, it was about the size of Athens. Some are of opinion, that the present Taurus is the same as Ecbatana, but there are now no vestiges of the famous citadel or palace. It is said by Sir John Chardin to have been, at the time of his visit, the second city in Persia, and at that time to contain 15,000 houses, 15,000 shops, 300 caravanserates, and 250 mosques; that the total population was 550,000, and that the piazzas exceeded those of Ispahan.

Persepolis.

Of all the ancient Persian cities, the ruins of Persepolis alone now exhibit to us a specimen of their palace architecture. It is situated in 30° 40′ N. latitude, and 84° E. longitude, in the province of Fars or Faristan, in a fertile plain about 40 leagues in length, and from 2 to 6 in breadth. There are, it is said, 880 villages in this plain, and 1500 in a circle 12 leagues round Persepolis.

Diodorus says, that Cambyses, after destroying the Egyptian temples, carried the spoils into Persia, and adorned the edifices he constructed by means of Egyptian workmen. But it is known that Cambyses died before he reached Persia, and therefore it is more probable these works may be attributed to his successors Darius and Xerxes; for Strabo states, that the kings of Persia, after decorating the palace of Susa, did the same to Persepolis and Pasargade.

No traces of the city.

Plate CLIII.

Three sides of the palace visible.

There are no vestiges of the city of Persepolis, but the extensive terraces, lofty columns, and Egyptian doorways of the palace, are singularly striking, (See Plate CLIII.) they are usually denominated the forty columns, but the traces of 205 were discovered by Le Brun, who spent three months in exploring, measuring, and delineating the ruins and sculptures. Of this superb building, the walls of three sides were then visible; the façade was 600 paces from north to south, and 300 from east to west. The 19 columns then standing were from 70 to 72 feet high, and 17 inches 7 nails in circumference. From the annexed Plates and the discussions under the Practice of Architecture, it will be seen, that these columns were different from the Egyptian: they appear too slender to support much weight, and therefore strengthen the probability of this being a summer palace, where temporary coverings were employed.

Sculpture.

Le Brun, after stating what is said by Diodorus Siculus Ptolemy of Alexandria, Strabo, Quintus Curtius, Stephanus, Ammianus Marcellinus, and Josephus, endeavours to prove, from the sculptures, that this was the palace of Persepolis, destroyed by Alexander 327 B. C. The dress and arms of the figures are partly Persian and partly

Median. The Persians offered horses to the sun, and oxen to the moon, as is shewn in the sculptured procession; here is also the tiara worn in the time of Cyrus, in the processions, where the principal lords were obliged to assist: (See *Xenophon.*) The umbrella was in use amongst the ancient Persians. The long robes, with foldings, is a Median dress.

Tombs of the kings.

Plate CLIII.

The tombs of the kings are found in one mountain to the south, and another to the north; the façade of the former is cut in the rock, and is ornamented with sculptures, Plate CLIII.; it is about 70 feet broad on the base; the part decorated with figures is about 40 feet broad, and as much in height; the rock extends beyond it on each side about 60 paces. The other tombs are similar to this. Le Brun found about 1300 figures of men and animals sculptured on these tombs; some of the men from 7.5 to 10.7 feet high; some had parasols or umbrellas over their heads; some were armed with lances; and many were combating lions. But for the particulars, we must refer to Plates CLIII. and CLIV., and the discussions under the Practice of Architecture.

Palmyra and Balbec.

Of the cities which rose to eminence in Persia and Syria under the Greek and Roman empires, the ruins of Palmyra and Balbec are best known to Europeans; but as their architecture is indisputably Roman, they will be noticed more properly when treating of the works of that great people.

Ispahan.

Ispahan, the present capital of Persia, is situated in the province of Irac, or Persia Proper, in 32° 25′ N. Lat. and 86° 40′ E. Long. Shah Abas, after the conquest of the kingdoms of Laz and Ormus, fixed his court there in 1620 and 1628. It is situated in an extensive plain, surrounded by mountains; the plain is watered by several rivers; of these, Zenderoud, after being joined by the Mahmood, passes by Ispahan, where it is crossed by three fine bridges; it is there about the breadth of the river Seine at Paris; some streets are broad and handsome, but many are narrow, crooked, and dirty; the public buildings are rather neat than magnificent. The great market-place and palace, which are 3-4ths of a league in circumference, and the buildings upon the bridges, make a good appearance: With regard to architectural construction, their external aspect points out distinctly the use of slender upright props, with flat and very slight coverings extended upon them, and projecting so as to protect those walking in the galleries from the sun.

Chinese architecture.

General remarks. Plates CLV. and CLVI.

These three countries, viz. Egypt, India, and Persia, as far as we know, comprehend all that is great and ingenious in the most ancient state of architecture. The countries to the north and west were without specimens of ancient art, and China possesses little which can establish a claim to architecture as a fine or ingenious art. The palace of Pekin presents only a large caravansera, with numerous courts and extensive galleries, having their trifling wooden posts highly japanned and gilt. The pagodas, Plate CLV. have each the appearance of tents piled upon each other; but in none of these structures is there to be found one feature expressive of great design or scientific skill. Through the richest parts of this great empire, which have lately been visited by Europeans, every private dwelling bespeaks poverty and an overstock of population; even their great wall, destitute of any claim to ingenuity, is only an instance of a numerous and timid people, terrified into the pitiful project of excluding, by means of a mass of earth, faced with masonry, their poorer and more warlike neighbours. If, therefore, this country, as has been asserted by an eminent writer, (Sir W. Jones), was originally a colony from India, this colony had not risen to that powerful state to enable them to adopt the sacred architecture of their parent country, before they were overrun by a people whose notions of building originated from the use of the tent, and whose habits led them to perform an infinite number of little things by almost individual independent exertions. Being situated at the eastern extremity of a continent, at a great distance, and, in many cases, separated by extensive deserts and vast ranges of mountains, from those western countries which afterwards became eminent for arts, or formidable by arms, China has long retained the same arts, nearly in the same degree of perfection.

Of Grecian Architecture.

Grecian architecture.

The next step in the history of architecture, leads us to consider it as practised in the Grecian states; and here, although during its early stages much uncertainty prevails, yet by the aid of ancient historians and scientific travellers of modern times, we are enabled to trace a tolerably connected view of the rise and progress of this school of the arts.

To conceive the Greeks totally ignorant of the state of architecture in Egypt and Persia at a period when those immediately adjacent empires had long existed in great splendour, had constructed edifices of the greatest magnificence, and were the countries from whence, if the Greeks were not originally colonies, they certainly very early derived the first rudiments of their knowledge, would be carrying credulity to an unwarrantable length. That the Greeks benefited by the architecture of Egypt and Persia, and even India, is rendered still more probable, by considering, that their early sages uniformly drew their information from these countries; that the commencement of the most rapid progress of architecture in Greece corresponds with the time of their connection with Egypt in the reign of Psammaticus; and that the pillars of the finest ancient edifices in each of those countries, in their shafts, capitals, and other ornaments, afford sufficient hints for a people less ingenious than the Greeks.

The Greeks received the elements of architecture from Egypt, Persia, &c.

But this singular people, situated in a rugged, and, in a great measure, insulated country, at the junction of Asia with Europe, and at no great distance from Africa, with the benefit of a fine climate, and unfettered freedom, appear to have collected, refined, and carried to a much higher degree of perfection, the knowledge and arts of those great countries to the east and south of them; and in what regards poetry, eloquence, painting, sculpture, and architecture, they produced in the course of a few centuries, specimens which succeeding generations have not been able to surpass.

which they refined and perfected.

Egypt had no wood.

Egypt had no wood, but abounded in mountains of granite, porphyry, and marble. These circumstances, and the extensive use which the earliest inhabitants made of natural and artificial caverns, must have led them to form their peculiar style of architecture.

Woods in Greece.

Greece, on the contrary, was possessed of forests, and the essential parts of their finest structures are evidently derived from the application of the materials which they furnished. The columns and entablatures correspond precisely with upright posts and horizontal beams of wood; and, above all, the pointed roof of their temples, which in Egypt and Persia had hitherto been flat, is peculiarly their own. In what regards decoration, the Greeks chiefly made use of the essential parts, and they bestowed their attention almost exclusively upon the external parts of the edifices.

The Greeks introduce the pointed roof.

General remarks.

These appear to be the general distinguishing features of Greek architecture; and, without excluding that people from the preceding labours of their neighbours in lesser points, it is evident that many essential parts are peculiarly their own; and scarcely had they attempted buildings of any considerable magnitude, when their judgment, skill, and taste, were displayed to a degree which placed the architecture of Egypt, Persia, and India, in the infancy of the arts. It was certainly greatly in favour of Greece, that, in process of time, fine marbles were employed; but, independent of the excellence of this material, there was more expression of mind in the formation of one statue by an eminent Greek sculptor, than in myriads of Egyptian hieroglyphics.

Of the Doric Order.

Doric order.

The first distinct character of the architecture of the states of Greece, has been denominated Doric, from the country in which it was invented. In the earliest specimens, the diameter of the pillars, in proportion to their height, bears a strong resemblance to those used in some of the Egyptian temples; but the triglyphs, metopes, and mutules, represent the disposition of wooden beams, and the ends of the rafters which compose the sloping roof.

Log-house a model for the Doric.

Plates CLVII. and CLVIII.

Conjectures respecting the Egyptian emigrants.

If we admit that the people amongst whom the Doric order took its rise, were colonies from Egypt or Phœnicia, dispossessing their more barbarous predecessors, and settling in a country abounding with forests, it is natural to expect, that, being at the time of their settlement possessed of a tolerable degree of information and skill, habitations similar to American log-houses would be constructed. This would at once furnish a correct model of the Doric order: and, if this was the case in private dwellings, a public building required only to be of increased dimensions, with some degree of decoration upon the essential parts; (see Plate CLVII. and CLVIII.) for which, as we have already observed, the Egyptian and Persian architecture furnished abundant hints. It may, however, be objected, that no trace of Egyptian mythology is to be found upon any work in Greece. In answer to this, it may be observed, that there are none upon the Egyptian pyramids; and besides, that, with respect to the causes of those emigrations to Greece, it cannot be reckoned an improbable conjecture, that the continued tyranny of the Egyptian priesthood, or kings, at last roused some bold innovator, who, rather than be controuled, removed, with a colony of similar characters, to Greece. If this is admitted as probable, we need not be surprised that the mythology and habits of the mother country were in a great measure changed; and, by comparing emigrants of this description, with those of a similar character in modern times, combining with these the local circumstances of those detached and intersected countries, and granting, (which history authorises), that various colonies, at separate times, settled in and formed the several states of Greece, we may easily conceive how such independent and turbulent characters were originally formed. But whether these speculations are admitted or denied, it is evident, that a building resembling a log-house has been the model of the Doric order; and it seems quite unnecessary to attempt to trace the art of building previous to that stage, since the habitations of all savages, even after they have obtained some degree of fixed residence, are uniformly found to be the cavern or the hut, according as their local situation is in a rocky or a wooded country.

Argolis, the cradle of the Greeks.

Doric order established at Argos,

and adopted in many temples. Plate CLVII.

dispositions of the columns;

its majesty.

The district of Argolis first received colonies who introduced civilization into Greece. It has been reckoned the cradle of the Greeks, the theatre of the events which distinguished their earliest annals, and the country which produced their first heroes and artists. It was, accordingly, in the temple of Juno at Argos, where the Doric order rose first to a marked eminence, and became the model for the magnificent edifices afterwards erected in the other cities, states, and islands. (*Vitruv.* b. iv. c. i. p. 68.) After the Doric order had been established in the temple of Juno at Argos, it was employed in the temple of Jupiter Nemeus, between Argos and Corinth; Jupiter Olympius, at Olympia in Elis; in a splendid triple portico in the city of Elis; and also in three temples in the same city, to Juno, Minerva, and Dindymene; at Eleusis, in the great temple to Ceres; in that of Minerva, at Sunium; and, above all, in the temple of Minerva Parthenon, (see Plate CLVII.); in the entrance to the Acropolis, and other public edifices, of great magnitude and splendour, at Athens. In many of the islands there were also temples of the Doric model: that of Apollo in the isle of Delos; Juno in Samos; Jupiter, Panellenius, Ægina, and Silenus, in Sicily; and innumerable in places of inferior note. Even in Ionia, it was employed in the temple of Apollo Panionius. Many of these edifices were of great magnitude. The temples of the Greeks were universally of an oblong form; in some, the porticos were at the ends only; in others, they were extended quite around the cell, some in single, others in double ranges; some were covered with roofs, others were left partly uncovered; and some of them were divided by ranges of pillars along the middle of the cell. The superstructure was placed upon a platform composed of three steps, which surrounded the whole edifice, and upon which the columns were all placed without bases. The number of columns were either 6 along the ends, and 13 along the sides, or 8 along the ends and 17 along the sides. (*Vitruv. Anacharsis*, Stuart's *Antiq. Athens*, *Ionian Antiq.*) When formed upon so large a scale, and the ranges of columns so distinctly insulated, the essential parts of the Doric order produced effects not to be exceeded for simplicity and majesty; even the imperfect fragments now remaining, appear to have far surpassed the expectations of persons well qualified to appreciate their merits. They were the chief embellishments of their cities; and their magnificent colonnades, by excluding the sun and rain, became the resort of the wealthy and idle, who associated for the purposes of business or pleasure; and also of those who delighted to engage in discussing the subjects of politics and philosophy.

its dimensions became more slender.

In the earliest specimens, the diameters of the Doric columns were very great in proportion to their height; that of the temple of Silenus, in Sicily, being only five diameters in height; but, in process of time, these relative dimensions were changed, and a considerably greater portion of delicacy introduced: The finest marbles were employed, and artists of the first talents not only formed the models of the edifice, and directed its execution, but also, under the strongest influence of rivalship and thirst of glory, they, with their own hands, clothed those edifices with sculptures, and enriched them with statues, expressive of more than mortal excellence.

This chaste and severe Doric style was, with very few exceptions, the only one employed in Greece or its European colonies in Sicily and Italy, until after the Macedonian conquest. (*Ionian Antiq.* vol. ii. Preface, p. 1.)

Of the Ionic Order.

Ionic order.

The Greek colonies which were planted in a part of the coast of Asia, named by them Ionia, being in possession of a rich country, with many cities well situated for commerce, became very populous and rich. Philosophy, science, and the arts, flourished there in so high a degree of perfection, that their claim to eminence has been reckoned to surpass that of any district of the mother country in the zenith of her glory, and they are even said to have finally adjusted and refined the proportions of the Doric order. See *Ionian Antiq.* Preface, vol. i. p. 3.

Plates CLVII. and CLIX.

Origin of the Ionic capital unknown;

supposed to be an imitation of rams horns,

and of curled bark;

where employed.

In Ionia, the temple of Apollo Panionius was built after the Doric manner; but that refined people, not satisfied with the simplicity of this order, invented another of a more delicate character, and named it after their own country, the Ionic. (See Plates CLVII. and CLIX.) They made the height of the column greater in proportion to its diameter than in the Doric; the capital was totally different in principle, the entablature was also changed in its members and proportions, and a base was added to the bottom of the column. Of the origin of this capital, we have no satisfactory account; Vitruvius, and later writers (who have all retailed precisely his relations,) reckon, that as the Doric was strong and masculine, the Ionians modelled their order with female delicacy, and that the volutes were taken from the curls of hair on each side of the face. It is difficult to conceive how the proportions of a Greek order of architecture could be taken from the human figure, to which it has no relation or resemblance; masculine and feminine have rather the air of figurative expressions, adopted by this lively people, in comparing these orders after they had been established. It has been, by others, with some degree of probability, alleged, that the shape arose from the custom of nailing rams horns upon the top of the posts. But the most simple and natural hint for the Ionic volute, which may be conceived as having fallen under the immediate notice of artists and workmen, seems to be the curling of the bark of a tree crushed down by a weight laid upon a rude upright post. The edifices constructed after this order were numerous and most magnificent. It was employed in the temple of Bacchus at Teos; Apollo at Miletus; Minerva at Priene and Tegea; and of Diana at Magnesia and Ephesus. It was likewise used in the temple of Minerva Polias in the Acropolis, in those of the Delphic Apollo and Æsculapius at Athens, and in a temple of Juno in Attica.

Temple of Diana at Ephesus.

That of Diana of Ephesus, the design of Ctesiphon the Cnosian, and his son Metagenes, (who wrote a treatise upon it,) is said to have been 425 feet in length, 220 in breadth, and 70 in height; it had a double portico all around the cell, erected by the contribution of all Asia. Xerxes, who destroyed all the other temples in his rout, spared this magnificent fabric. It was burnt by Herostratus during the night in which Alexander was born. It was rebuilt after a design of Dinocrates; Canachus the Sicyonian, a scholar of Polycletus the Argive, made the statue 124 years after Xerxes destroyed the first, and 365 before the Christian æra. See *Vitruv. Ionian Antiq.* vol. i. c. 3.

Of Diana at Magnesia.

Origin of the Pseudodipteros.

The temple of Diana at Magnesia was constructed under the direction of Hermogenes. He made the general dimensions the same as for the dipteros or double range of columns; but, in order to afford more space in the porticos, he omitted the inner range: By that means a clear space was left between the outer range and the wall of the cell, and he thereby established the Pseudodipteros. He wrote a treatise upon this temple and that of Teos, (*Ionian Antiq.* vol. i. c. 11.) Vitruvius speaks with great veneration of the talents of this architect.

Temple of Minerva at Tegea, by Scopas.

The temple of Minerva Ulea at Tegea, designed and erected under the direction of Scopas, was of singular construction: The peristyle which surrounded the temple was of the Ionic order, the cell was divided into three aisles by two rows of Doric columns, and over these were placed others of the Corinthian order. The sculpture upon the two pediments was by the hand of Scopas himself. Upon the one was represented the hunting of the wild boar of Caledon, where, among a great number of figures, were those of Hercules, Theseus, Pirothous, and Castor; upon the other, the subject was the combat of Achilles and Telephus. *Anacharsis*, vol. iii. p. 71.

Of the Corinthian Order.

Corinthian order,

Plate CLX.

invented by Callimachus.

Egypt and Persia afford hints of this order.

The artists of Grecia Proper, perceiving that, in the Ionic order, the severity of the Doric had been departed from, by one happy effort invented a third, which still much surpassed the Ionic in delicacy of proportion and richness of decorations: this was named the Corinthian order. (See Plate CLX. The merit of this invention is ascribed to Callimachus, an Athenian sculptor, who is said to have had the idea suggested to him, by observing Acanthus leaves growing around a basket which had been placed, with some favourite trinkets, upon the grave of a young Corinthian lady; the stalks which rose among the leaves having been formed into slender volutes by a square tyle which covered the basket. It is possible that a circumstance of this nature may have caught the fancy of a sculptor who was contemporary with Phidias, (Stuart's *Antiq. Athens*, Pref.) and who was doubtless, in that age of competition, alive to every thing which promised distinction in his profession. But, in the warmth of our devotion for the inspiration of Greek genius, we must not overlook the facts, that, in the pillars of several of the temples in Upper Egypt, whose shafts represent bundles of reeds or lotus bound together in several places by fillets, the capitals are formed by several rows of delicate leaves. (See *Denon.*) In the splendid ruins of Vellore in Hindostan, the capitals are also composed of similar ornaments; and it is likewise well known, that the Persians, at their great festivals, were in the habit of decorating with flowers the tops of the pillars which formed their public apartments: It is therefore not improbable that these circumstances, after so much intercourse with those countries, might have suggested ideas to Callimachus, which enabled him to surpass the capital of Ionia. The whole fabric of the Corinthian order is composed with a great delicacy of taste. It is admirably fitted for the most highly ornamented states of architecture, and is strongly expressive of the refinement and excellence to which the Greeks had carried their taste and skill in architecture and sculpture.

The Greeks having invented and established three orders, with each a separate character, calculated for edifices, gradually ascending from the most simple to those which were highly ornamented, completed a distinct and perfect school of architecture, to which there remained nothing to be added.

Sir W. Chambers despised the Greek architecture.

From the account given of the various edifices constructed after each order, it is evident, that the passion for magnificent buildings and fine sculpture was carried to a great height. It so far exceeded the apparent extent of the means of the Greek states, that an eminent architect and architectural writer of our own country, (Sir W. Chambers,) disputed their existence. Unfortunately for his speculations, the labours of late scientific travellers, perfectly qualified, and of undoubted veracity, have furnished correct drawings of many remains, which fully justify the accounts of former times, and are highly deserving the encomiums which have been bestowed upon them.

Competitions of the states of Greece.

Value attached to architecture.

After the defeat of Xerxes, the Greeks obtained the full possession of liberty. They applied with great success to the cultivation of philosophy, science, and arts. They became not only sensible, but vain, of their decided superiority over the Egyptians and Persians; and as each state endeavoured to maintain a perfect independence, and many attempting to acquire a superior influence, it is very conceivable that their jealousy, rivalship, and continual contention, would strongly influence the arts of architecture and sculpture; while the insatiable rage for distinction, which pervaded all orders of men, animated, to a particular degree, those artists, who, by their works in architecture and sculpture, expected, and frequently acquired the applause of their countrymen and posterity. The value attached to works of this nature, may be judged of from the city of Ephesus refusing to suffer the temple of Diana to be inscribed with the name of Alexander the Great, although this prince offered to purchase that honour by defraying the whole expence attending its erection; from the Athenians rejecting a like offer from Pericles, with regard to the splendid and extensive edifices with which he had ornamented Athens. (*Ionian Antiq.* vol. i. c. 111.); and from the city of Gnidia refusing to part with one statue, (the Venus of Praxiteles,) although King Nicomedes proposed to free them from tribute if they complied with his request.

Temples erected at the common expence of all Greece.

The art extended to the Greek colonies.

Temples appear to have been the only property which these turbulent states could agree to have in common, and this union enabled them to construct edifices of great magnitude and splendour. They had many of this description, built and maintained at the expence of confederated states, and even of all Greece: Such were those at Delphi, Delos, Ephesus, Olympia, Eryx, &c. These temples had territorial revenues, and were enriched by private donations. Being secured by the laws of war, they were banks wherein states, and even individuals, deposited treasure; and, instead of the priesthood, the management was vested in the magistrates, (*Ionian Antiq.* vol. ii. Pref. p. x.) The Greek architecture prevailed in the countries where that people extended their influence along the coast of Asia. Alexander and his successors introduced it into Egypt, and most probably in the cities he built on his route to India. To the westward it spread as far as Sicily, Italy, and the south of France.

Besides temples, the Greeks constructed many other public edifices of great magnificence: These were the Forum, Stadium, Theatre, and Tomb. But as these require a full and extensive discussion, they will be taken up under their several appellations.

Of private dwellings.

Plate CLXI.

The private dwellings of the Greeks were generally mean; but, from the description preserved by Vitruvius, a drawing of which, taken from Palladio, is given in Plate CLXI. it appears, that the villas of some of the principal men were extensive and highly decorated; and, by admitting strangers to occupy separate complete suites of apartments, they were contrived for a very perfect intercourse of society. That this was required in Attica, is easily to be conceived from the great number of strangers which, for many years, resorted to Athens; and they would also be necessary in those countries which were adjacent to the Amphictyonic temples. Besides these causes, there can be no doubt but, in the districts which carried on mercantile transactions, such as Athens, and Corinth in Grecia Proper, almost all the cities of Ionia, of Asia, and also among the islands to the westward of Greece, that the accumulation of wealth would produce effects similar to what takes place in other countries, and would distinguish the habitations of its possessors.

Period of its most rapid progress in Greece.

The Greeks appear to have made the greatest progress, and constructed the most magnificent of their edifices, during a period of time commencing with the age of Solon and Pythagoras, and ending with that of Pericles, being about 300 years. It is worthy of remark, that the period at which architecture began to flourish most in Greece, corresponds precisely with the reign of Psammaticus in Egypt, who encouraged and benefited by the assistance of the Ionian and Carian Greeks, and induced them to establish colonies upon the Nile. See *Herod.* b. ii. *Ionian Antiq.* vol. ii. chap. v. p. 19.

The art declined after the time of Alexander.

After the time of Alexander, the Greek manners were blended with those of Asia. The sublime spirit of independence, and high notions of superiority, which had hitherto exalted their characters, and rendered them capable of such unparalleled exertions, if not quite subdued, was deeply contaminated; and although they long continued to be the instructors of their Roman conquerors, it is from this æra that the declension of the pure Greek architecture may be dated.

OF ROMAN ARCHITECTURE.

Roman architecture.

Spoils of Sicily.

THE Romans, through every period of their history, from the first inconsiderable efforts of their infant tribes, to the complete establishment of a most extensive empire, were continually engaged in foreign or domestic wars. The principle of their government being at first of a popular cast, it was to military skill, and a simple but impressive eloquence, that their whole attention was devoted, and upon which their national character was formed. Until the state had reached the zenith of its glory, by subjecting all the nations, including Britain, to the west, Macedonia and a part of Persia to the east, and the northern parts of Africa to the south, they preserved the utmost simplicity of manners, remained in a great measure ignorant of what are denominated the fine arts, and, of course, set no value upon, but rather despised them. All to the north and west of Italy being in a barbarous and rude state, it was not until the Romans had extended their conquests over the colonies of Greece, Greece itself, and a part of Asia, that they had an opportunity of becoming acquainted with fine architecture, sculpture, and paintings. Plutarch relates, that Marcellus brought the spoils of Sicily, consisting, in part, of the most valuable statues and paintings of Syracuse, on purpose to adorn his triumph, and ornament the city of Rome, which before his time had never known any curiosity of this kind; and he adds, that Marcellus took merit to himself for being the first who taught the Romans to admire the exquisite performances of Greece.

Architecture rose hastily to extravagance.

But when the most formidable rival states had been destroyed or subjected, the wealth which all at once came into the possession of the Romans affected their manners; and having not only the productions of Grecian genius, but the artists themselves, within their power, the transition was into the extreme of luxury and splendour.

The art rose gradually in Greece.

In Greece, the arts rose from small beginnings, from the unremitting efforts of rival states and artists; they were, therefore, natives of the country, while the manners of the inhabitants were polished, but natural: but to the Romans who merely acquired them by power; they were emblems of superiority lavishly and indiscriminately employed. It was evidently under this impression that the Romans greedily seized the Corinthian, being the most gorgeous of the Greek orders, and employed it almost exclusively in all their public edifices, and private dwellings.

But, even for some time after Marcellus had introduced specimens of Grecian art, and out of the spoils of Sicily built and embellished the Temple of Virtue and Honour, it does not appear that much impression had been made upon the Roman people; and although, about forty years afterwards, at the triumphs which Paulus Emilius obtained for the conquest of Macedonia, it is said the first day was scarcely sufficient to exhibit the images, paintings, and colossal statues, carried in 250 chariots, (*Plutarch*,) yet it was not until after the return of Sylla from the Mithridatic war, (which was 120 years after the triumph of Marcellus,) that specimens of fine buildings can be distinguished. It was only fifty years previous to this that an edifice of marble was first erected at Rome; but, in the consulship of Quintius Catullus, it is said 100 marble temples were erected. Pompey erected a theatre, and Julius Cæsar the temple of Apollo, the porticos, library, and mausoleum. *Ionian Antiquities*.

One hundred marble temples in Rome.

From this period, the progress in luxury and extravagance was rapid: In a few years, the villas of the principal men (see Plate CLXI.) were extensive and highly decorated: Those of Lucullus surpassed even eastern magnificence.

Plate CLXI.

The magnificent and politic Augustus, confirmed in power, and with the command of unbounded wealth, exceeded his predecessors so far, as to boast, that he found Rome composed of brick, and changed it to marble. The following are the principal edifices erected during his reign: The temple and forum of Mars the Avenger, the temple of Jupiter Tonans in the capitol, of Apollo Palatine, with public libraries, the portico and basilicæ of Caius and Luvius, and the porticos of Livia and Octavia; (see *Suet.* c. 28.); and besides these,

Edifices by Augustus.

In the Year of Rome

720. The curia, schools, a noble portico round the temple of Jupiter and Juno, with a library adjoining.
723. Statilius Taurus finished an amphitheatre at his own expence.
724. The temple of Minerva, called Chalcidicos, was built of brass.
725. Augustus built a mausoleum for himself and family.
726. Agrippa, the friend and son-in-law of Augustus, built, or rather altered and embellished, the Pantheon. See Plate CLXII.
727. Agrippa dedicated the septa, for containing the comitia tributa.
728. He erected the portico of Neptune, and near it built the temple and basilicæ of that deity; he added the magnificent portico to the pantheon, and behind that edifice built the thermæ for exercises in the Lacedemonian manner.
730. He constructed the great theatre of Marcellus, to the memory of Marcellus, son of Octavia, sister to Augustus.
734. He brought the aqua virginis to Rome, by an aqueduct fourteen miles in length.
748. He presented to the sun the great obelisk of Sesostris, brought by him to Rome.

Pantheon. Plate CLXII.

Temple of Faunus. Plate CLXIII.

During the reign of Claudius, the very curious temple of Faunus (see Plate CLXIII.) was built upon the Celian Mount. It was of a circular form, and had internally two rows of Ionic columns, with arches springing immediately from the capitals. The upper windows had each a column in the middle, with arches also springing from the capitals; and these two arches were inclosed by a semicircular arch, which had its springing upon the jambs of the window, and, rising higher, left a considerable space between it and the two before-mentioned small arches; in which space there was a circular opening. This is particularly noticed as an early and distinct type of what was afterwards named Saxon, Norman, and Gothic. See Desgodetz' *Ancient Rome*.

In Nero's time, the city having been destroyed by fire, was rebuilt with more regularity and splendour. The accounts of the extent and splendour of his golden house exceed credibility. The strict œconomy of Vespasian enabled him to construct the temples of Peace (see Plate CLXIV.), and the Colisæum, two of the greatest and most magnificent edifices at Rome, the latter being 580 feet in length, and 470 in breadth. The elliptical amphitheatre of Titus was upon an equally large scale, being 564 feet in length, 467 in breadth, founded on 80 arches, and rising with five successive orders of architecture to the height of 140 feet; the outside incrusted with marble, and decorated with statues; having 60 rows of seats, 64 vomitories, and calculated to contain 80,000 persons at one time: The extensive baths of Titus were equally splendid. During the time of Domitian, the temples of Jupiter Capitolinus and Minerva were erected. The excellent Nerva contributed to adorn Greece, by his liberal conduct to Herodes Atticus, a descendant of Cimon and Miltiades, who having discovered a vast treasure buried under an old house, and conscientiously informed the emperor that it was too much for the use of a private man, was nobly told, "to abuse it then, for it was his own." Herodes having obtained for his son Herod the prefectorship of the free cities of Asia, this young magistrate immediately employed his treasure in architectural improvements. He, in four years, built the stadium at Athens, 600 feet in length, all of white marble; also a theatre, which he dedicated to his wife Regilla. He restored the odeum of Pericles; he built a temple to Neptune in the isthmus, a theatre at Corinth, a stadium at Delphi, and a bath at Thermopylæ. At Troas he supplied the city with water at a great expence; he built an aqueduct at Canusium in Italy; and the people of Epirus, Thessaly, Eubœa, Bœtica, and Peloponnesus, also partook of his bounty. The forum of Trajan (by Adrian) was expressive of his great character: it was of a quadrangular form, surrounded by colonnaded porticos, and entered by four triumphal arches. In the centre stood his celebrated column, 140 feet in height, where the principal actions of his reign were represented in exquisite sculpture, and have remained the truest chronicle of his time. His successor Adrian seemed to have journeyed over the provinces, in order to build and restore cities and public edifices: He built the beautiful city of Antinopolis in Egypt. At Athens, he completed the great temple of Jupiter Olympius, which had 128 Corinthian columns, each 60 feet high; restored the walls and gates, and by inscription claimed the city as his. He supplied the city of Corinth with water. He was himself an architect, so zealous and vain, that the great Apollodorus fell a victim to an unguarded reflection upon his plan for the temple to Rome and Virtue. That his taste was open to just criticism, is rendered probable from the whim of his having all the styles then known introduced in his famous villa. He likewise built the great wall across Britain, between Newcastle and Carlisle.

Temples of Peace and the Colisæum. Plate CLXIV.

Herodes Atticus.

Forum and column of Trajan.

Temple of Jupiter Olympius at Athens.

With the continued influx of wealth from the numer-

Architecture extended beyond propriety.

ous, rich, and extensive provinces, the rage for magnificence kept pace; and public and private buildings increased much beyond the bounds of propriety. To debauch the people, public shows had been introduced, and theatres of vast magnitude constructed; habits of luxury required superb edifices for exercise and bathing; the forums were much increased in size and splendour; the single column had been employed as a recording monument; and the introduction of the arch had created many new structures, especially the triumphal arch and the aqueduct.

Its progress in the provinces.

This rage for building was not confined to Italy, but extended over every province of the empire. It appeared the most effectual way in which the different emperors, governors, and commanders, could gratify their vanity, and establish their authority; and their rapid succession led to an increase of the number in every quarter, from Palmyra and Balbec in the east, (where their architectural works were splendid and vast,) to the remote province of Britain in the west; but after the time of the Antonines, the people became vitiated, all dignity of character disappeared, and every thing proceeded from one excess to another without taste or arrangement.

Theodosius.

Justinian.

Their architecture, which never was pure, had degenerated into extravagance, and was overloaded with gorgeous ornaments. The talents of Dioclesian could neither reform the empire nor its architecture. He resigned the government of the former, and, in his palaces and baths, left specimens of the degenerate state of the latter. From this period architecture shared the fate of the empire, and, excepting some solitary instances in the reigns of Theodosius and Justinian, there is nothing deserving of attention; though, in order to preserve some idea of the style of those times, and establish a connection with a new school of architecture which succeeded, or rather for a considerable time interrupted the progress of the Roman, it is necessary to mention, that the third church built by Constantine was that of St Paul, on the road to Ostia; of which, the 40 columns enclosing the great aisle, 24 of blue and white marble were taken from the mausoleum of Adrian; that the church of St Paul, without the gates of Rome, was erected under Theodosius; and that St Sophia at Constantinople, was erected under Justinian. See Plate CLXXIII.

Plate CLXXIII.

Romans indebted to the Greeks.

The Romans were so much indebted to the Greeks for all that relates to architecture and sculpture, that they have little claim to any original ideas upon those subjects. Being found in so perfect a state as to repress all thoughts of rivalship, the Romans were contented to plunder and imitate. In the theatre of Marcellus and in the Coliseum, the Doric and Ionic were both introduced, but, with a very few exceptions, the Corinthian order only was employed by the Romans; and, as if not left by the Greeks sufficiently expressive of riches and magnificence, they loaded every member with ornaments unknown to the inventors. They united the Ionic and Corinthian into an order they named the *Composite*, and stripping the Doric of its finest features, they formed their Tuscan. When the particular members could receive no more ornaments, they had recourse to varying the outlines of their structures into every shape which could be produced by the union of circles or triangles. See Montfaucon's *Antiq.* vol. iii.

The arch introduced by the Romans.

To one important feature in architecture, the Romans appear to have an indubitable claim, that is the arch. The ancient Egyptians, Persians, and Hindoos, were entirely ignorant of its construction; and in no instance have the Greeks, previous to the Roman conquest, made use of arches, either in the external or internal faces of their buildings. It has been said, that arches over drains have been observed in the ancient temple of the sun at Athens, and that of Apollo at Didymus. If that were clearly ascertained, it would determine the merit of the mere invention to the Greeks; but it is evident, that the people never considered the arch of any importance as an external feature, nor were aware of the advantages which might be derived, by extending it over considerable openings, for in no instance have they in this manner employed it; and, notwithstanding the splendid and expensive works of Pericles, it was left for the Romans to construct a stone arch over the small river Cephisus, upon the great road to Athens. If, therefore, we should not be fully justified in attributing to the Romans the merit of the first invention, they assuredly had that of introducing arches into general and extensive use, and, by this means, creating a species of architecture unknown to the Greeks. The arch in their hands, was employed in extensive vaultings and domes, in triumphal arches, bridges over rivers, and in aqueducts for conveying water to cities. Thus far the arch was an important acquisition in the building art; but not satisfied with this, they hastened to introduce it in façades of Greek architecture, the distinguishing features of which being straight lines, the circular outlines of the arch were discordant, and distracted the mind between a style formed by the employment of timber beams, and another which could only be composed by a number of separate stones, placed in a position very different from that in which timber was used. This therefore became a glaring defect in the Roman architecture, and distinguished it widely from the simplicity of the Grecian.

Plates CLXII. CLXIII. CLXIV.

Dioclesian.

The specimens, exhibited in Plates CLXII. CLXIII. and CLXIV. will shew in what manner the Roman style was, at various periods, employed in public and private buildings. We shall therefore conclude this outline of its history, by observing that the power, wealth, and vanity of the Romans, led them to increase the number, magnitude, and decorations of their edifices to a degree almost incredible. The dexterity of execution in the pantheon, Trajan's column, the palace and baths of Dioclesian, and the triumphal arches, are evidence how well qualified their workmen were, at all those periods, of bringing the particular parts to any degree of perfection; but the directing mind was from the beginning deficient, and constantly became more depraved. The Greek style, which had been polluted in its introduction to Italy, had its forms at last so distorted and overwhelmed with injudicious ornaments, that scarcely any resemblance was left to distinguish its origin.

OF GOTHIC ARCHITECTURE.

Gothic architecture.

This name has been given to a school of architecture very different from either the Greek or Roman. Its origin has perhaps hitherto hardly been satisfactorily ascertained, but it certainly continued till the sixteenth century, when it was supplanted by the revival of the Roman style. It was only at the time of its extirpation that the appellation of Gothic was applied, in token of the contempt in which it was held by the school of Palladio in Italy, and Jones in England.

The fate of this style of architecture has been as singular as its principles of construction. It was, during a few centuries, practised over most of Europe with a degree of ardour, and to an extent which rendered its effects truly magical. From the zenith of its glory it was, by a very rapid transition, reduced to the state of degradation we have just alluded to.

After the expiration of about two centuries, men of science have again begun to discover the excellence of its principles, and men of taste to perceive the beauty of its forms. These violent transitions have led to much investigation and discussion, by persons well qualified for the task, such as Wren, Walpole, Gray, Warton, Wilkins, Carter, Bentham, Grose, Murphy, Knight, Dallaway, Whittington, Milner, and Sir James Hall.

Writers.

Various opinions as to origin.

One opinion is, that the pointed arch, and most of the delicate features of Gothic architecture, were furnished by the Saracens and Moors; a second finds, that the changes took place by the gradual deviation from the Roman manner, and that most of the features have arisen from the whim of Italian architects; a third ascribes the merit of the finest Gothic almost exclusively to the gradual changes introduced by the architects of England; while Sir James Hall has, with much taste and ingenuity, shewn how this style may have originated in a way totally independent of any other mode of architecture. Under these circumstances, we shall first endeavour to give a cursory but connected view of the progress of this architecture in Europe, from the time of the decline of the Roman empire to the 16th century; and then make such general observations as seem calculated to enable the reader to form his own judgment. We conceive this of sufficient importance to deserve his serious attention. It is a proof, that even where an art has been brought to a perfection, as in the case of Greek architecture, which seemed to preclude all farther improvement, yet a change of circumstances will produce another mode totally different, but equally perfect; and it is incontrovertible evidence, that the boundaries of human ingenuity are not to be easily limited.

Observation.

Roman architecture declined in the time of Dioclesian.

From the time of Vespasian, the Roman architecture began to be less pure. During the reign of Trajan it had considerably declined; and, in the splendid edifices of Dioclesian, forms had been introduced (Adam's *Spalatro*) not only foreign to the best style, but sufficiently different to afford hints for some features of the Gothic; such as arches springing from the top of capitals, of columns without any intervening entablature, and consols supported by figures projecting from the wall.

Gothic architecture employed in ecclesiastical edifices.

Gothic architecture having been employed almost exclusively in ecclesiastical edifices, this investigation must of course be directed chiefly to buildings of this description. The oldest Christian church now existing is considered to be that of St Paul, which was built by Constantine without the gates of Rome. This is also the earliest instance of a Christian church, in which the arches are raised upon round columns instead of square piers. Gibbon says, that the palace of Theodosius affords the oldest specimens of the Gothic; so that, coeval with the incursions of the Goths, the Roman architecture had been almost completely changed. The confusion which ensued towards the final extinction of the empire, led almost to the total neglect of the arts. The consequences of which, were the ignorance and incapacity of artists and workmen. These evils had also, by the incursions of the Goths and Huns, been spread over all Greece; and the effects upon the arts were manifest, from the failures and clumsiness of the best Greek architects. Justinian was able to select artists to construct his great church of St Sophia at Constantinople.

St Sophia at Constantinople.

Ancient basilicæ used or imitated.

At the time Constantine established Christianity, many of the basilicæ, or courts of justice, in the great cities of the empire, were converted into Christian churches, and being convenient for the accommodation of great assemblies, the new churches were built in the same form. This form was oblong, and had pillars within the walls of the covered cells, thereby dividing the whole breadth into three or four aisles. The principal entrance was at the west end; and the east end, where the tribunal was placed, was of a circular form. See Bentham *on Saxon Churches*.

Here, then, we find established the oblong form, with the space between the walls, divided by two rows of columns into three aisles. Upon the columns, arches are immediately erected in a connected range, to receive an upper wall which supports the roof. The chief entrance is also at the west end, and the east end is of a circular shape. An addition was made, which completed the Latin cross, and perfected the ground plan of a Christian church. The remains of ancient edifices, part of which were converted into churches, had still some influence in guiding the workmen of that age in their clumsy operations. They had preserved the principles and habit of arching vaults, especially the kind which is now denominated groins. They are formed by two arches intersecting each other at right angles, and, in many instances, springing from four points only. By this means, the diagonal lines formed by the intersection of the two arches, cross each other at the centre of the vault. It is of importance to notice this circumstance, because it afterwards became one of the principal features of the Gothic style.

Latin cross introduced.

Groin arches.

Rome being at the head of the Christian church, and for several ages possessing unbounded influence over all the rest of Europe, created a great intercourse, and afforded the ecclesiastical dignitaries ample opportunities of becoming early acquainted with the forms of the Italian churches. Their zeal and vanity introduced similar edifices into the several countries where they resided, and, through their means, the rage for building churches in a short time became general and excessive.

Dignitaries travelled to Rome.

Church building became extravagant.

This ecclesiastical architecture, drawn from the same source, and diffused through the several countries of Europe by the same description of characters, a general resemblance was preserved; yet the architecture of each country in this, as in other matters, from a variety of local circumstances, soon came to be distinguished by peculiar features. That of Italy retained the greatest resemblance to the Roman manner, and was seldom overloaded with ornaments. In the northern countries, the decorations were more redundant. In all of them, the attention was bestowed chiefly upon the western façade. At Pisa, Orvietto, and Sienna, in Italy, circular arcades and porticos are frequent. Some are composed of columns, taken from Roman works, and others imperfect imitations. In Spain, the architecture was strong and massive in its outlines, but decorated with minute ornaments of great delicacy, borrowed from the Moors. See Dallaway's *Observations*, pp. 2—6.

In Italy, the resemblance to Roman architecture preserved.

Western façade.

During the reign of Charlemagne, many magnificent churches were erected; and the extent of his dominions served to give some degree of regularity to the operations of architecture. This, especially in France, formed no inconsiderable æra. He is even said to have introduced it into that country; and it is certain that the cathedral of Rheims was erected during the reign of his successor in 875.

Charlemagne.

Crusades.

The most remarkable æra in the history of this school of architecture, was the crusades to the Holy Land. This apparent frenzy and delusion, which threatened to unpeople Europe, and overwhelm Asia, and which was actually productive of so much bloodshed and misery, had also the effect of introducing into the countries of the west, all the knowledge and arts collected from the east and south, into a district bounded by Greece and Palestine, and which, from the contentions of the Turks, Saracens, and the remnants of the Western empire, seemed on the point of extermination even from thence, and being of course lost to mankind. But the intercourse of 174 years, taught the rude warriors of Christendom the benefits of more polished manners, and made them acquainted with the improvements and arts of those eastern countries.

In those days of religious zeal, it cannot be doubted, that every thing which related to the improvements in the forms and decoration of ecclesiastical buildings, would be carefully attended to, by the prelates from different countries, who were connected with the several expeditions; and that they would, on their return home, endeavour to introduce their newly acquired information. See Felib. *Rec. Hist.* p. 165.

Fraternity of free masons.

Dionysiacs.

During the Crusades, another circumstance took place, which also contributed much to the perfection of their ecclesiastical buildings. Some Greek refugees, Italians, French, German, and Flemings, united into a fraternity of builders, and procured papal bulls and particular privileges. They assumed the name of free masons, and travelled from one nation to another, where their services were required. Their government was regular. Adjacent to the building which was to be erected, they constructed a camp of huts; a surveyor governed in chief, and every tenth man, called a warden, overlooked nine. (Wren's *Parentalia.*) This establishment, similar to the Dionysiacs of Ionia, upon whose model it was probably formed by the Greek refugees, was the means of creating great dexterity in the workmen, and of making the surveyors become perfectly well acquainted with every circumstance which related to the plans and decorations. From the different national styles which were formed and closely adhered to, it is probable that the ecclesiastics furnished the designs; because if the surveyors had done so, the same plans would have been repeated in the several countries where they were employed. Still it was of the first importance, to have men who understood plans, and workmen who were familiar with all the minutiæ of execution. See Free Masonry.

Italy.

Germany.

France.

Under all these circumstances, ecclesiastical buildings of great splendour were soon erected in the several kingdoms and states upon the Continent. In Italy, at Florence, Venice, Pisa, Sienna, Orvietto; in Germany, and amongst the Flemings, at Vienna, Strasburgh, Nuremberg, Antwerp, Ghent, and Brussels; and in France, at Rheims, St Denis, Amiens, Notre Dame, Verdun, Laon, Lezoux, Chartres, Rouen, and Seez, were very early and splendid specimens.

Campanile towers separate.

Mixture of styles.

In Italy, the nearest resemblance to the Roman manner, such as circular porticos and arcades, was preserved, but exuberance of decoration seldom occurs; the western façade engrossed the chief attention. Upon the centre of the transepts, cupolas were placed, and the campanile towers were always separate buildings. There are no spires in Italy, but the towers of Florence and Venice are slender, lofty, and beautiful. In the Baptista of Pisa, which was erected in 1152, the lower Greek manner is mixed with the German Gothic; in it are Corinthian pillars, circular arches, Gothic pinnacles, sharp pediments, enriched with foliage, and terminated with a trefoil. Such instances of Gothic features, were not common in France before 1220, at St Denis.

Profusion of decorations.

In France and Germany, the architects have also exhausted all their genius upon western façades, and in many of them have produced very magnificent and striking effects; but they much exceeded the Italian structures in profusion of decorations. Here numerous pointed and sculptured pediments, niches, statues, and canopies, were lavishly distributed; in many of them, one circular window occupied the space between two towers richly ornamented with clustered pinnacles, and in several of them were very lofty spires. At St Stephens, Vienna, and Strasburg in Germany, and Rouen, Constance, and Bayeux in France, the spires are just a continuation of the tower diminishing from its base.

Spires pyramidal.

Elements of fine church architecture.

To compose a perfect church, a French critic of Gothic architecture proposes to adopt the portal and west front of Rheims, the nave of Amiens, the choir of Beauvoirs, and the spire of Chartres. See Dallaway *Ob. on English Architecture.*

Of Gothic Architecture in Britain.

Britain.

Having given a general view of the most distinguishing æras and leading features of Gothic architecture upon the continent, we shall proceed to consider its progress in England, whose claim to the most perfect style of this school is generally admitted. In doing this, the learned and masterly investigations of the before mentioned authors, will enable us to trace a regular and connected progress; and we shall, for the sake of perspicuity, be as minute as the nature of our work will admit.

Agricola constructed temples.

Claudius.

When Agricola had subdued the northern parts of the island, he endeavoured to instruct and civilize the inhabitants. By means of the artificers attached to the army, many Roman edifices were constructed, and the numerous remains of temples and baths which have been discovered, are evidences of both public and private structures having been carried to a very considerable degree of perfection. This it was natural to expect during a residence of 400 years. The stone dug up at Chichester, which records a temple dedicated to Minerva by one of the companies of workmen, shows, that such buildings were executed long previous to Agricola, upon Claudius having reduced the southern parts of the kingdom, and probably soon after the temple to Claudius at Malden, to Minerva at Bath, and to Jupiter and Diana at London, were erected. See *Ornaments of Churches considered.*

Twenty-eight Roman cities built in England.

Hume relates, that during the dominion of the Romans, 28 considerable cities had been built, besides a great number of villages and country seats.

The Romans had, it appears, made very little progress in the instruction or civilization of the inhabitants; their subjection had been so complete, and their condition rendered so servile, as totally to annihilate their spirit, and debase their character; so that when the Romans withdrew from the island, the knowledge and practice of the arts were extinguished, and the inhabitants relapsed into helpless barbarism.

Whithorn in Galloway, 448 A. D.

Bingham (B. viii. p. 10.) says, that about the year 448, Bishop Ninian of Glasgow built an episcopal church on the confines of England, at Whithorn in Galloway, which was probably the labour of Roman workmen.

City of Canterbury.

As the Romans remained in Britain 88 years after the death of Constantine, it is, considering his zeal, to be expected, that some Christian churches were, during this time, erected; accordingly Bede mentions, that two were built in the city of Canterbury, one of which, on the east side of the city, was dedicated to St Martin, and given by Ethelbert, after his conversion, to St Augustin. See Wharton's *Essays.*

During the period in which the Saxons subdued, or extirpated, the antient Britons, and established themselves in England, a dreadful scene of devastation took place; the Roman cities and structures were wholly destroyed, and scarcely a vestige of their improvements was suffered to remain. But in the course of 100 years from the de-

First St Paul's, London.
St Peter's, York.
Weremouth.
Rippon.
Hexham.
Ely.

parture of the Romans, when King Ethelbert was converted to Christianity by St Augustine, the zeal for erecting ecclesiastical buildings took place. He founded the first St Paul's in London, and St Andrew's in Rochester. In 627, Edwin founded St Peter's in York, which was built of hewn stone, with spacious porticos. The Abbot Biscopius went over to France to procure workmen to build after the Roman manner; on his return he built St Peter's church in the monastery at Weremouth. In about a century after the conversion of Ethelbert, Wilifred, bishop of York, brought over eminent builders and artists from Rome, Italy, and France; he glazed the windows of York cathedral, and built the conventual church of Rippon in Yorkshire; which Edius says, he raised with hewn stone to a great height, and supported by various kinds of pillars and porticos. But his most sumptuous edifice was the cathedral church of Hexham in Northumberland. Richard, prior of Hexham, in whose time, 1180, it was standing, says, "That the foundations of this church were laid deep in the earth for the crypts and oratories and passages leading to them, which were then with equal exactness contrived and built under ground. The walls, which were of great length, and raised to an immense height, and divided into three stories or tiers, he supported by square and various kinds of well polished columns; and the arch of the sanctuary he decorated with historical representations, imagery, and various figures in relief carved in stone, and painted with a most agreeable variety of colours. The body of the church he encompassed about with aisles and porticos, which both above and below he divided with great and inexpressible art by partition walls and winding stairs; within the staircase, and above them, he caused flights of steps and galleries and passages leading from them, both for ascending and descending, to be so artfully disposed, that multitudes of people might be there, and go quite round the church without being seen by any one below in the nave. Moreover, in the several divisions of the porticos or aisles, both above and below, he erected many most beautiful and private oratories of exquisite workmanship; and in them he caused to be placed altars in honour of the blessed Virgin, St Michael, St John the Baptist, and the holy apostles, martyrs, confessors, and virgins, with all decent and proper furniture to each of them. It appeared, that of all the nine monasteries over which that venerable bishop presided, and of all others throughout England, this church of St Andrew in Hexham was the most elegant and sumptuous, and that its equal was not to be met with on this side the Alps." Wilifred gave great encouragement to skilful builders and eminent artists; he was himself well skilled, and was the chief director, in concert with those excellent masters he had brought from Rome; and it is probable, that the church and monastery of Ely, founded by St Etheldrida, were built under his directions; as we are informed by Ely the historian, that he spent a considerable time with her settling the economy of the convent. The connection with Rome continued to increase, as did the power and influence of the clergy, as well as their zeal for erecting ecclesiastical buildings.

Croyland.
York rebuilt.
Alcuin.
Alfred.
Old abbey of Westminster.

In 716, Croyland Abbey in Lincolnshire was founded by Ethelbald. In 767, Archbishop Albert rebuilt St Peter's of York. His first employment was in the capacity of master of the celebrated school of York, where he taught grammar, rhetoric, astronomy, natural philosophy, and divinity. He afterwards visited Rome, and many of the most eminent seats of learning on the Continent. On his return he was made Archbishop, and finding his church in a ruinous condition, he took it wholly down, and rebuilt it in a most sumptuous manner; his architects were Eanbald and the famous Alcuin, two of his own church. During the 9th century, the incursions of the Danes were destructive to the arts and many of the edifices already erected; and it was not until peace and good order were restored by Alfred, that any regular progress could be made in any of the arts of civil life. That inimitable prince extended his cares into every department which could promote the welfare of a well-regulated state; but the defenceless situation in which he found the kingdom, led him to direct the building art to military purposes, such as building and repairing walled towns, erecting castles, and constructing ships. About 960, Edgar is said to have founded forty monasteries, chiefly those which had been destroyed by the Danes, and he built the old abbey of Westminster.

Ramsay in Huntingdonshire.

In 974, the abbey of Ramsay in Huntingdonshire was completed; it was in the form of a cross, with side aisles, and two towers, one of which was at the west front, and the other was supported by four pillars in the middle of the building, where it divided into four parts, being connected together by arches extending to other adjoining arches, to keep them from giving way. This appears a new mode among the Saxons, as none of those which are more antient are described as having any thing of the form of the cross, or having towers above the roof. See Bentham's *Essays*.

Westminster Abbey rebuilt.

Early in the 11th century some change took place, for Edward the Confessor is said to have built Westminter Abbey, according to a new mode which was introduced into the kingdom, (*Mathew Prior*, p. 226.); and about this time it appears, that some excellent artificers flourished in France.

Saxons.
Saxons copied from the Roman buildings.
Moors.

The Saxons were reckoned one of the most fierce and warlike of the German tribes, with a very imperfect knowledge even of agriculture. When they conquered England, devastation was carried into the most remote corners, the public as well as private edifices were reduced to ashes, and the natives were slaughtered or carried into slavery; these people were, therefore, without any knowledge or habits of architecture. This knowledge was acquired after they were in full possession of England, had been converted to Christianity, became attached to fixed residence, and had accumulated property: (Hume's *History of England.*) The only regular architecture which could have come under their observation, was in the remains of Roman works, which had escaped or withstood their former fury. This must have attracted their attention, when they became disposed to construct buildings of any consequence; but their workmen were without knowledge or experience: (Somners' *Antiquities of Canterbury*, p. 146.) It was therefore absolutely necessary to have recourse to France or Italy, which was constantly done by those ecclesiastics, who had come to the resolution of building Christian churches: (*Ornaments of Churches considered.*) The Saxon architecture having been chiefly copied from the Roman works in Britain, the style which was practised during their age, in Italy, had a strong resemblance to it, and was constantly denominated the Roman manner. During the first age of the Christian era, when the Roman best style had been much departed from, the architecture of both the Christians and Moors was characterised by solidity and bulk, and particularly for having great numbers of round short pillars. It has been observed, that there is a near relation between the architecture of the Moors and that described in Scripture; and that in Barbary and the Levant it has continued the same: (Dr Shaw's *Travels*, p. 273.) One of the principal

History.

No buttresses in the Saxon style.

Arches semicircular.

Mouldings.

mosques of Cordova is distinguished by its capaciousness and a great number of low massive pillars: (Ray's *Travels*, p. 487.) The Saxon style is conformable to these relations. The general form of the earliest Saxon churches was that of the Basilica, being a simple oblong, with a portico and ambulatory. The chief entrance was the west end; and at the east end was a circular recess, resembling the Roman tribune, but now appointed to receive the Christian altar. Additions were afterwards made, which completed the form of the cross; and towards the termination of the Saxon government, towers were erected in the west front, and over the centre of the cross. The outer walls were of a great thickness, and had no buttresses. Within the great churches, there were sometimes three stories, which were occupied by the arcade, gallery, and windows. The pillars were short, massive, and round. The arches, in arcades, doors, and windows, were all semicircular. The principal door-cases were decorated with pillars and sculptured capitals. Round the arches were mouldings of great variety, with bas reliefs. The mouldings consisted of the indented zig-zag like Etruscan scroll, small squares alternately deeper flourished, with small beads, usually on the capitals of pillars; and on some of their latest works, was a carving like a trellis in broad lozenges. The base mouldings and capitals, though of exact dimensions, similar in mass, were much varied in the minute parts: (Dallaway's *Observations*. Carter's *Ancient Architecture in England*.) Though it would be difficult to mention many entire edifices now remaining, which are composed wholly of Saxon architecture, yet it may, in numerous instances, be pointed out in particular parts. Of different edifices, Elkstone and Quisington, in Gloucestershire, and the whole of Tickenocte church, near Stamford, are Saxon; also, the nave of Oxford cathedral, and sundry parts of St Alban's and Durham; enrichments of door-cases and windows will be found in Barfreston, near Canterbury; Durham cathedral and palace, Tutbery in Staffordshire, Romsey Hants, and Rochester. The door-way, east end of Kenelworth church, has the caput bovis, fret mouldings, and patera in the spandrils,—ornaments peculiarly Roman. *Archæologia*, vol. x.; and Lyson's *Gloucestershire Antiq.*

Edifices of Saxon architecture.

History.

Norman conquest.

The manners of the Anglo-Saxons were rude; they were ignorant of letters, unskilled in mechanic arts, and addicted to intemperance, riot, and disorder. The conquest by the Normans put the people in a situation to receive slowly from abroad the rudiments of science and cultivation, (*Hume.*) The Normans were moderate and abstemious, but much disposed to pomp and magnificence in their dress, and likewise in their public and private buildings. They introduced civility, learning and arts, and restored religion from the neglected state into which it had fallen. Bentham's *Essay*.

Edifices in Normandy.

Edifices in England.

Previous to the invasion of England, the Normans had constructed magnificent edifices in Normandy; and owing to the frequent intercourse with that place, and the introduction of Normans into the highest situations in the English church by Edward, who had been bred at that court, and partial to its manners, led to an imitation of the Norman style, especially in the Abbey church of Westminster, and in that of St Peter at Gloucester, both of which were erected during this reign.

Norman arch.

Character.

The Normans, as soon as they had completely subdued England, and established themselves in every part of the kingdom, prosecuted the erection of ecclesiastical edifices with great zeal and success. Their style was similar to that of the Saxons; and the chief difference consisted in their being of larger dimensions, in their having plain, but more lofty vaulting, circular pillars of greater diameter, round arches and capitals, with carvings much more elaborate and various; but in both there was a total absence of pediments and pinnacles, tabernacles, or niches with canopies. Dallaway's *Observations.*

Era from 1066 to 1154.

The era of the Norman architecture is reckoned from the conquest, in 1066, to the death of King Stephen in 1154; and their exertions will appear evident, when it is considered, that, during this short period, every quarter of the kingdom was ornamented by their works; and that fifteen English cathedrals, whose origin can be ascertained, exhibit undoubted features of Norman construction. The cathedrals of Canterbury and Battle Abbey were two of the finest structures of the conqueror's reign; and of the following, the bishops, whose names are annexed, were the architects.

Norman edifices and architects.

	Cathedrals.	*Bishops and Architects.*
1077 to 1107	Rochester, Canterbury, and Peterborough,	Gundulf, Bishop of Rochester.
1086 — 1108	Old St Paul's, ...	Mauritius of London.
1107 — 1140	Old Sarum, ...	Roger of Salisbury.
1115 — 1125	Rochester, ...	Ernulf of Salisbury completed Gundulf's works.
1123 — 1147	Lincoln rebuilt, ...	Alexander of Lincoln.
1129 — 1169	St Cross and Ramsay in Hants, ...	Henry de Blois of Winchester.
1154 — 1181	. . . .	Roger, Bishop of York.

During the erection of these works, Norman architecture was brought to perfection, and their magnitude had much exceeded that of their predecessors; also, in many instances, in delicacy and elegance of design, as in the fine specimens in Winchester cathedral, especially in the portal of the ancient Sacristy, between the east cloister door and south transept, which is the work of Bishop Walkelin, cousin to the conqueror, and finished in 1093; and there is also in the upper part of the south transept of the same cathedral some round intersecting arches, placed by way of ornament upon the outside. These, which were part of the original work, were finished in 1093, prior to the first crusade, and are perhaps the earliest authentic instances of the pointed arches in this kingdom. But in the church of St Cross, near Winchester, in the easter end, constructed by Henry I. 1132, are richly ornamented Saxon arches intersecting each other; which intersections are open quite through the wall, constituting highly pointed windows to the number of 20.

Churches belonging to abbeys.

Of the churches in this style, belonging to the greater Abbeys, the following are fine remains: Malmsbury, Wiltshire; Dunstable, Bedfordshire; Castle Acre, Norfolk; Wenlock, Salop; St Botolph's, Colchester. These magnificent works are a proof of the power, influence, and talents of the ecclesiastics of that period. The Roman pontiffs about this time arrived at the utmost plenitude of authority, and they were ably supported by prelates of that time. Amongst all the revolutions of civil government, the interests of the church remained protected, and continued regularly to extend its influence. This enabled them to execute works which appear sufficient to require the whole revenue of a state.

Pointed style commenced, A.D. 1154.

Lancet style perfected.

During the reign of Stephen, that is, from 1135 to 1154, the arches became slightly pointed: the heavy round pillar was divided and clustered, and by degrees converted into the tall slender pillar, supporting the sharply pointed arch, distinguished by the name of lancet; but still many ornaments of the preceding era continued to be used. In the reign of the third Henry, the cathedrals of Westminster, Salisbury, and Ely, are evidence of the perfection to which this elegant style had then been carried.

Distinguishing features.

Fine spires.

The distinguishing features of this style are tall and slender pillars, some of them, as in the nave of Worcester cathedral, are bound by fillets at certain distances, and insulated and clustered into a single column, with narrow lancet windows, and roofs upon simple cross springers; the arches sharply pointed, and the windows increased to three lights: There was sometimes a combination of circular and pointed, and still a mixture of the old ornaments; but perhaps the most striking of all the features of this period, is the lofty and finely tapered spire, which, in 1222, was constructed of timber, covered with lead, upon the lofty tower of Old St Paul's cathedral. The tower itself was 260 feet high, and the spire being 274, made the total height 534 feet This was under the reign of Henry III. See Stowe's *Survey of London*.

Norman style totally gone.

Under Edward I. every feature of the Norman style was totally rejected. Slender pillars of Purbeck marble were adopted. These were united under one capital, decorated with the leaves of the palm tree, and the pillars and arcades were modelled into an extreme of lightness.

W. de Wykeham.

Knots of foliage, statues, and flying buttresses.

Early in the reign of Richard the II. under the celebrated W. de Wykeham, additional boldness and decorations were thrown into the style. The capitals were constructed and sculptured with more ingenuity; the vaults were studded with knots of foliage at the intersection of the ribs; the western front was enriched with statues; and the flying buttresses, formed of segments of circles, were rendered highly ornamental. Dallaway's *Observations*.

Tracery.

Clustered columns.

Windows, tracery, and painted glass.

The ribs had also formed a considerable degree of tracery upon the vaults. The small columns were at last not placed separate from the body of the column, but, being united, composed it. The windows were greatly enlarged; they were divided by stone mullions, and spread, in the upper part, into many beautiful and fanciful ramifications. The eastern and western windows, in many instances, occupied the whole breadth of the nave, and rose nearly as high as the vaultings. And these windows, which were now filled with painted glass, exhibiting portraits and historical subjects, produced a magical effect, with which mankind had hitherto been unacquainted. In the cathedral and St Mary's chapel, now Trinity parish church at Ely, are pillars and windows of this style, and the chapel is reckoned one of the most perfect structures of that age. Bentham's *Essays*.

Crown of Becket's tomb, suggested the Louvre, Ely, and Canterbury.

It has been thought that the crown of Becket, in Canterbury cathedral, suggested the plan of the Louvre, of Ely, and Canterbury, which are fine specimens of this style; and that the crosses, erected by Edward I. afforded a model for the canopies, denominated tabernacle work. Dallaway's *Observations*.

Era 1272 to 1399.

With regard to the era of this style, the first appearance of the pointed arch was during the reign of Stephen (1135 to 1154); but the Norman features were not wholly rejected till Edward I. (1272 to 1307); and the termination of this pure style may be placed about the commencement of the fourth Henry (1399), so that the works which exhibit this particular style were executed in the latter end of the 13th and the beginning of the 14th century.

Crockets.

Much sculpture.

The distinguishing features have already been mentioned; but it is necessary to add, that the arches of the windows and niches, were ornamented with crockets tied at the top, in a knot resembling the blossom of the Euphorbium; the central towers became more lofty, and more ornamented; the cloisters, altars, screens, canopies, shrines, and even external western fronts, were highly enriched with sculptures, and the tapering spire was brought into use.

Edifices in this style.

It is impracticable and unnecessary here to enumerate all the instances where this style was executed; for it was extended to ecclesiastical buildings in every quarter of the kingdom; but the following are specimens which will convey a satisfactory idea of its excellency: The western parts of York, Peterborough, and Litchfield; the addition at Lincoln; the naves of Canterbury, York, Winchester, and Exeter; the choirs of York and Gloucester; and, for correctness of proportions and richness of decorations, the screens of Abbot Whitehamstead at St Alban's, and Bishop Fox at Winchester, deserve to be noticed.

Style changed.

Era 1399 to 1509.

Walls thin and high.

Parapets and pinnacles open work.

Pendants.

Images of angels.

Fan-work.

Edifices.

From the accession of the fourth Henry to the death of Henry the VII. in 1509, that is, during the course of the 15th century, the style of architecture was again completely changed. Mr Walpole is of opinion, that the Sepultural Saelta of the archbishops of Canterbury were the models for the style of this century. The walls were made of great height, but remarkably thin. The towers were ornamented with panelled arcades in every part of their height; and the parapets and pinnacles were formed of open embattled work. The vaultings of the roof were constructed with great ingenuity, and were made to unite with the groins formed by the arches over the windows; they were also formed into pendants of singular shape and workmanship. Over the high altar, instead of decorations, composed of architectural members, or imitations of leaves or flowers, images of angels and musical instruments in full choir were introduced. The cloisters, which had hitherto remained quite plain, had now their roofs overspread with tracery, which, rising from the springers, took the form and appellation of fan-work; and even the windows of these cloisters were filled with painted glass. Of this style, the finest specimens are, the chapel of King's College, Cambridge, begun by Henry VI., and finished by Henry VIII., and the sepultural chapel of Henry VII. at Westminster. The number and variety of ornaments, among which the armorial bearings had long been introduced, the exquisite delicacy of workmanship, and the extent of windows filled with painted glass, in walls of incredible thinness, but, above all, the singularity of the roof, produces a wonderful degree of surprise and admiration.

Profusion of decoration.

From this period, an insatiable disposition to vary and increase decorations, already so profuse, the dreadful havoc which took place at the Reformation, and the inclination which began to prevail of introducing the ancient Roman style, (which, early in the 16th century, had been revived in Italy,) led to all the confusion and despicable intermixtures which took place for almost a century.

Having now given as full an account of the state of architecture, from the decline of the Roman style to the period of its revival, as a work of this nature admits of, the reader is referred for farther particulars to the authors who have been occasionally mentioned. The Rev. Mr Dallaway, more especially, has given a very full, masterly, and well arranged view of the subject.

General observations.

The reader having now before him an account of the changes which the art underwent during the before mentioned period, and the leading historical circumstances connected with it, he will readily perceive, that always in Italy, and in Britain, till 1135, the great features are those of a depraved Roman style. He will recollect, that, about this time, the intercourse with the East, by means of the Crusades and settlements in Palestine, was frequent and extensive;—that, about this time, a corporation of builders, consisting of Greeks, Italians, French, Germans, and Flemings, united, under the sanction of papal bulls, to construct ecclesiastical buildings; and, for this purpose, travelled wherever their labours were required. The information acquired by the ecclesiastics who visited the East, when united with the experience and dexterity of this incorporated school of builders, and supported by the influence the church had acquired, will account for the improvements which took place, and for the expedition with which such a number of edifices, of so extraordinary magnitude and splendour, were every where erected. It will also open a wide field for speculation, respecting the probable causes for the variations in the manner which took place.

For the pointed arch, which, in the pure Gothic, is accounted a governing feature, there will be found a striking resemblance in the intersection of the beautiful Saxon or Norman arches in the cathedral of Winchester, constructed previous to the first Crusade; and in the east end of the church of St Cross, near Winchester, erected by Bishop Blois, 1132. There are twenty highly pointed windows which enlighten the chancel, formed by the intersection of circular arches. On the inside of the wall, the pillars which support these arches, and also others at Winchester, are divided into tall slender forms. Long, narrow, and lancet-pointed arches, are formed by the intersections of the circular arches, without pillars or mouldings, which are placed, by way of ornament, on the upper part of the outside of the south transept at Winchester. These casual occurrences may perhaps be reckoned to have afforded sufficient hints to ingenious men to improve into more perfect forms; and when united with the taste for minute and delicate ornaments, as practised by the Moors, and also with other ideas collected from the architecture of Egypt and Syria, and impelled by every motive which religious zeal, vanity, caprice, and the most ardent spirit of competition could impose, will probably, to many, afford a satisfactory explanation for the changes and improvements which took place, from the period of the most simple to that of the most magnificent and luxurious style of this school.

But such interest has Gothic architecture of late excited, that not only the periods in which it appeared have been disputed, but the claims of rival kingdoms, as to priority, have been contested with much ability and zeal. The late Mr Whittington has endeavoured to prove that the original hints came from Asia, and that France preceded and surpassed England in producing fine specimens of this school of architecture. While Dr Milner has boldly claimed the merit exclusively for our own country, and has, with much distinctness and assiduity, traced the progressive steps by which the changes took place. These two able men having taken masterly views of the architecture of the two countries, we cannot resist presenting our readers with a sketch of their statements, referring to their valuable performances for more perfect information.

Whittington.

Mr Whittington begins by observing, that the Roman architecture was only pure from the time of Augustus to that of Hadrian and the Antonines; that, in the works of Dioclesian, may be found arches springing from tops of columns, consols supported by figures projecting from the face of the wall, and even the zig-zag moulding. He says, that Constantine founded churches at Rome and Byzantium in the form of the ancient Basilica, of which there were 19 in Rome; and that Santa Croce in Gerusaleme at Rome, is the only specimen of the architecture of Constantine, and is thought to have been originally open at the sides. St Paul's, without the gates of Rome, built, in its present form, in the time of Valentinian and Theodosius and Arcadius: near the end of the fourth century it was inclosed on all sides. St Paul's is the best specimen of the manner of building, and St Clement's of the internal distribution of the first churches.

Gaul, 3d century.

Gregory of Tours.

In the 3d century there were seven bishops sent to Tours, Orleans, Thoulouse, Narbonne, Paris, Limoges, and Auvergne; and Constantine built a church at Auvergne. In the 5th century Gregory of Tours relates, that Pepetuus bishop of Tours built a church over the tomb of St Martin, 155 feet in length, 60 in breadth, and 45 in height; that it had 120 columns, 52 windows, and 3 doors in the sanctuary, and 5 in the body of the church. Naumatius, bishop of Auvergne, also built his cathedral in form of a cross, with aisles on each side which terminated in a round apsis; the walls of the sanctuary were incrusted with marble; it was 150 feet long, 60 wide, and 50 high, had 42 windows, 70 columns, and 8 doors.

Clovis.

St Genevieve.

Form oblong, sometimes a cross.

The manner of execution.

Leo, bishop of Tours.

St Denys.

Clovis, being converted, built many churches. He founded the abbey of St Peter and St Paul (near St Genevieve) without the walls of Paris in 507, also the church of St Peter at Chartres, and St Mesenin near Orleans. His son Childebert built the abbey of St Germain des Prez near Paris. It is said that the only remains of these works are the tower of St Germain des Prez, and that of St Peter at Chartres. The general form was oblong, with a semicircle at the east end. They were sometimes in form of a cross; the roof was supported by pillars of stone and marble, and covered with lead or gilt tiles; the altar and covered ceiling of apsis were incrusted with marble and Mosaic work, as were sometimes the western front; the walls were embellished with sculptures, relieved with painting; the windows were frequently glazed; there was a pediment in the west front perforated with a circular aperture, and afterwards with a rose window. The plans, it is said, were often made by the abbots, and their convent assisted in carrying on the work; in sundry times the ecclesiastics performed carving, smelting, painting, and mosaic. Leo, bishop of Tours, was a great artist, especially in carpentry. St Eloy, who was first a saddler, then a goldsmith, and at last bishop of Noyon, built the monastery of Lolognac near Limoges, but was most noted for shrines of gold, silver, and precious stones, especially those at St Denys and St Martin of Tours; he died in 668. The greatest work of this century was St Denys, by Dagobert, son of Clothaire. Pepin began to rebuild it, but it was completed by Charlemagne, and dedicated in 775. The vault of the crypt under the east end, and the great entrance of the present church, is said to be part of the work of Pepin and Charlemagne. It appears that, in the course of the 8th century, stone towers and belfries became common in France.

Charlemagne.

Low state of the arts.

The palace of Charlemagne at Aix la Chapelle and the church were decorated with the marbles of Rome and Ravenna, and executed probably by Italian workmen. The churches built in the time of this prince, were proofs of the low ebb of the arts. Here magnificent and beautiful pillars supporting pitiful arches, high walls disfigured with uncouth paintings and glittering Mosaic work, pillars of different forms placed in the same row, pavements composed of various and uneven fragments, timber of roofs left naked without ceiling or ornament. The churches of St Vincent and Anastasius, and St Laurence in Verona,, and St Agnes without the city, erected about this time at Rome, are specimens of this debased taste; and the internal walls of old St Peter's at Rome, were painted in this rude manner under Formosus I. in 890.

Louis's Edifices.

Rumalde, king's architect.

Under Louis, the successor of Charlemagne, the churches and monasteries of St Phillebert, St Florent upon the Loire, of Karoffi, Conches, St Maixant, Menat, Manlieu in Auvergne, Moissac, St Savin in Poictou, Nouaille, St Theotfroy, St Paixant, Lolognac near Limoges, St Marie, St Radegonde d' Agnani, St Laurent and Caunes. It was during his reign that Ebo bishop of Rheims began to rebuild his cathedral, on which occasion the king sent his own architect, Rumalde, to carry on the work.

Normans destroyed churches, &c.

Abbey of Clugny.

The Normans began their irruptions, and destroyed a great many churches, *i. e.* St Owen in Rouen in 842, and the cathedral of Chartres in 850. A few years afterwards they destroyed St Genevieve at Paris, set fire to St Germain des Prez, and ruined St Martin of Tours. Charles the Bald attempted in vain to check them. Notwithstanding these irruptions, sundry abbeys were built under his reign, as the abbey and church of St Benigne at Dijon. The most celebrated edifice of this period was the abbey of Clugny, built about 910, by Bermo abbot of Balme. Maignard, a canon of St Genevieve, is said to have built the entrance to that church in the reign of Hugh Capet.

Robert the Pious enabled Morard the abbot of St Germain des Prez to rebuild the church of his convent on a larger scale. St Genevieve was also restored, and a cloister added; he also made preparations to build a cathedral at Paris on a magnificent scale. Many religious structures were benefited by his encouragement.

Cathedral of Chartres.

Dimensions.

The cathedral of Chartres was one of the greatest works of this age. It was said to have been completed by its bishop Fulbert, who died 1028. Its length was 420 feet, breadth 108; the nave 48 feet wide, with side aisles 18½ feet wide, and 42 feet high; on each side the choir the aisles are double, and the transept, which is 210 feet long, contains aisles. There are seven chapels in the Chevet, and the crypt and lower church are very regular: This seems the first instance of regular and magnificent arrangement in France. Some reckon it to have been completed by Thierri or Theodoric in 1048. The northern part was built afterwards by Jean Cormier, physician to the king.

Rheims.

The church of St Remi at Rheims was founded by the abbot Hermez, and consecrated in 1049 by Leo IX. and the new cathedral of Scoz was completed (1050) under Azon a monk.

Clugny.

The abbey of Clugny, the largest ecclesiastical monument in France, was erected about this time. The abbot Odilo collected various marble columns by means of the Rhine; and Duromer, it is said, constructed a cloister. The present church was probably begun by the same prelate, but the chief part was built by Hugh his successor, about 1069. It was consecrated in 1169 by Innocent II. the length 620 feet. It has two transepts, the upper one is 200 feet, the lower 120 feet in length.

Style of the 11th century.

The style of the 11th century was the same as that of the preceding, but the works were upon a larger scale. With a few exceptions, the oldest buildings now existing in France may be traced to this æra, *i. e.* St Germaine des Prez, St Benigne at Dijon, Chartres, La Charité upon the Loire, and Clugny.

Saxon in England inferior to Norman.

Barbarous imitations of the Gothic continued all over Europe, with some difference in features. Saxon churches in England were inferior in magnitude to the Norman, and the latter differed from those near Paris and in the south of Europe. The Norman churches, though longer, were rude, and had less skill in sculpture than the French artists, who had improved by imitating the Roman works.

Abbey of St Stephen at Caen.

The abbey of St Stephen, raised by William the Conqueror at Caen, and that of the Holy Trinity, founded in the same city, by his queen Matilda, are the chief examples of the Norman introduced into England.

Crusades.

Pointed arch.

Notre Dame.

The Crusades began to rouse mankind, and light was brought from the East. During the 12th century the pointed arch made its appearance in the French edifices, and, in a short time, the Roman or Lombard style was discontinued. Amongst the earliest instances, was that at St Denis, begun by abbot Suguin, in 1137. About the same time the monastery of the Knights Templars at Paris, bore marks of the Gothic; the tower was built by Huber, treasurer of the order, who died 1222. In 1177, Stephen the abbot determined to rebuild St Genevieve, which he completed before he was made bishop of Tournay in 1192. About this time, Maurice de Sully, bishop of Paris, began to build the eastern part of the cathedral of Notre Dame, but it was not completed for two centuries afterwards. The choir of the cathedral of Lyons seems of this period, and the collegiate church St Nicholas at Amiens, was begun about 1192, and the portal finished in 1200.

At the beginning of this century the old Lombard mode was practised; towards the middle this was mixed with pointed arches; and, before the end of the century, the ancient heavy style was every where discontinued, and the new unmixed Gothic adopted.

Change of style.

Abbey of Bec in Normandy.

Rheims.

In the thirteenth century, ecclesiastical architecture reached its greatest perfection in France in 1212. Ingolramne was employed by abbot Richard to rebuild the abbey church of Bec in Normandy; he was succeeded by Waultier de Meulan, who finished it; but it was burnt and restored under Pierre de Caniba, about 1273. Rheims cathedral began to display the new style, and at Lyons the body of the cathedral was completed. The cathedral of Amiens, the pride of Gothic architecture, was erected by Robert de Lusarches, Thomas de Carmont, and his son Reynault. Notre Dame was carried on by Jean de Cholles; and Pierre de Mentereau was employed on the chapel and refectory of St Germaine des Prez, and Saint Chapelle, at Paris. Eudes de Montreuil was celebrated for his scientific skill and bold conceptions; he accompanied St Louis to the East, and on his return was employed in the churches of St Catherine de Val des Ecoliers, St Croix de la Bretonnierre les Quinze-Vingts, the White Monks, the Mathurins, the Carthusians, the Cordeliers, and the Hotel Dieu, at Paris; likewise the Notre Dame at Mantes; he died 1289. The vaulting of the roof in the latter astonished Lauflet and Gabriel for its boldness; the height from the pavement being 96 feet.

St Antoine, &c. in Paris.

The church and abbey of St Antoine, near Paris, the churches of Filles Dieu, the Jacobins, the Carmelites, and the Cordeliers of Fauxbourg St Marcel, were also

History.

built by order of the king; and likewise the abbeys of Lio, near Milan; of Longchamp, near St Cloud; and St Mathieu, near Rouen; the greater part of the abbey church of St Denis, the Hotel Dieu of Vernon, Pontoise, and Compeigne; and the church and abbey of Manbuison. The church of Notre Dame des Unes, in Flanders, was begun by Pierre, the 7th abbot, and completed in 1262, by Theodoric: the whole church was built by the monks themselves, assisted by the lay brothers and their servants. Robert de Coucy completed the cathedral of Rheims, and the church of St Nicaise for boldness and symmetry he surpassed all his contemporaries. Jean Rauy, an architect and sculptor, was employed 26 years upon Notre Dame.

Robert de Coucy.

In the reign of Charles V. the monasteries of the Augustines and Celestines were built at Paris; a magnificent chapel, on the model of the Sainte Chapelle, at Paris; and many important additions were made to the Louvre. Charles V. was the founder of the Royal Library of France; he placed 120 volumes in one of the towers of the Louvre. The abbey of Bonport was erected about 1387.

In the 14th century, windows in leaves.

Vaults rich.

The 14th century differed considerably from the last. The windows, instead of foils and roses, branched into leaves, and there were richer decorations upon the vaultings of the roof. Similar changes took place in England, where they were carried to a higher degree of perfection.

In the 15th century, France did not equal England.

The taste of the 15th century was inimical to architecture; it resembled that in England and other countries in the present day. There were many instances of tracery, especially in chapels and sepulchral monuments. The chapel of Charles de Bourbon, archbishop of Lyons, in the cathedral of that city, is a fine instance, and one of the latest works in the Gothic style produced in France. Charles de Bourbon died in 1478. The distracted state of France at this period prevented them from equalling what was done in England.

Restoration of Roman style begun.

The Italian artists about this time began to restore the Roman style, and painting and sculpture soon arrived at excellence; but in architecture, though the Gothic was abandoned, there was little of the pure Roman style in that which was adopted. It consisted chiefly in imitations of the Abarasque designs of Raphael, which he had copied from the frescoes of the baths of Titus and Livia, and introduced into the galleries of the Vatican, which met with applause in a generation too much accustomed to profusion of ornament to relish simplicity.

Having thus traced the progress of this school of architecture from its introduction into France to the reign of Louis the XIIth, which marked a total abandonment of it, Mr Whittington next proceeds to comment upon the principal edifices, and compare their merits with those of buildings of the same age in England.

Observations and comparisons.

St Germain des Prez.

Of St Germain des Prez, it is remarked, that the interior is low and gloomy, lighted by small windows, as in our Saxon buildings; but in the arches and columns of the choir, which have remained since the time of Morard, the general proportions, and especially those of the capital to the shaft, approach very nearly to the Roman Corinthian, while others are a sort of Abarasque, composed of birds and griffins, still retaining the Corinthian leaves and volutes. Here columns support a series of circular arches, excepting the circular arcade at the east end of the church, where they are pointed, in consequence of the arrangement of the pillars, which are placed nearer to each other than where the colonnade is a straight line. The same circumstance is found in the crypt at St Denis; in the choir of the church of La Charité sur Loire, and at the east end of Canterbury cathedral, built between 1180 and 1185, where "the arches are some circular, and some mitred, for the distances between the pillars here diminish gradually as we go eastward. The arches being all of the same height, are mitred (pointed) to comply with this fancy, so that the angles of the eastern ones are very acute. See Gostling's *Canterbury*, p. 221.

St Genevieve.

History.

With regard to the abbey of St Genevieve; in the time of the Celts, an island in the river Seine, surrounded by forests, was first resorted to for shelter. The habitations did not extend beyond the L'Isle de la Cite, which still retains the metropolitan church and palace of justice. This place was enlarged by the Romans, especially Valentinian and Grotian.

Clovis at first resided in the Roman palace, but afterwards erected one on rising ground near the south suburbs, and added a church to St Peter and St Paul, which was not finished at his death in 511. This church was afterwards named St Genevieve, after a pious lady, in whom the Parisians had great faith.

Description.

The abbey church has probably the same disposition, and partly the same walls, as in the time of Clovis. It is without transepts, but has a circular termination. It was only repaired by Robert the Pious, or by Abbot Stephen. The façade is remarkable for its nakedness; its portal consists of three pointed arches, with small columns and capital, decorated with ivy leaves; above the middle door is a rose window. The other windows are long and lancet-shaped, the whole enclosed by a massive plain pediment. The nave is separated from the nave aisles by eight columns; four, larger than the others, their capitals truly Lombard, being a mixture of leaves, birds, &c.; the four smaller ones have Acanthus leaves; upon these caps rest clusters of small pillars and pointed arches, erected by Abbot Stephen, to support the roof. This is an example of the exact shape of the early French churches, with narrow lancet windows, which are rare in that country.

St Denis.

History.

St Denis, or St Dionysius, was reckoned the first preacher of the gospel to the Gauls. The persecutors ordered his body to be thrown into the Seine, but a Pagan female got possession of it, buried it in a field near Paris, and sowed the field with corn; she afterwards erected a small monument over it, to which the Christians resorted, and built a church there, about the middle of the third century; but from its having been rebuilt on a larger scale, and endowed by Dagobert, he generally passes for the founder. Felibien places the commencement of the building in 629. It was oblong, with a circular termination, having marble colums within, and a profusion of Mosaic work: he also built cloisters and offices to the monastery. This church of Dagobert was taken down, and another built by Pepin and Charlemagne, and dedicated in 775. The Normans plundered it in 865. Suger was elected abbot in 1122, being nominated regent of France by Louis VII. on his departure for the Holy Land. He restored, added, and embellished it, especially the west front and towers. He discovered excellent stone in a quarry near Pontoise, and procured timber from the forest of Chevreuse, which he marked with his own hand. It was dedicated in 1140.

St Denis had lands in England, *i. e.* Tinton, in Oxfordshire; Rotherfield, in Sussex; and Deerhurst, in Gloucestershire. This edifice is externally very lofty, but the west front is deficient in majesty. The chief portal is arched semicircularly, and adorned with sculpture. The walls have alternately round and pointed arches in half relief, on small pillars, similar to those of Purbeck employed in England: the height of the towers is unequal. In St Denis, there are three eras of architecture: 1st, The

History.

Three eras of architecture.

Earlier examples of pointed arches than in England.

oldest ornaments in France. 2d, Lower church, beneath the chapel of St Denis, is part of the fabric by Pepin and Charlemagne. 3d, The pointed arch. The chapels of the Chevet and western front, are the work of Suger; also the pavement and painted glass. In his time, the columns were Lombard, but the pointed arch appears in every part of his works, which were about the middle of the 12th century, and are earlier examples than any to be found in England,—St Cross, near Winchester, built in 1132 and 1136, being considered as too dubious to be admitted as an instance. In England, the earliest mixed style appeared in 1154, under Henry II. The first used in vaults was begun by Roger of York in 1171; the vestibule of the Temple church in 1184; the western tower of Ely 1189; the choir of Canterbury 1175 and 1180; and two western towers of Durham in 1233; the latter being exactly in the style of Suger, at St Denis.

Description.

The nave, choir, and transepts of St Denis, by Eudes Clemont, and Mathieu de Vendosine, between the years 1231 and 1281, are equal to Amiens in magnificence and delicacy. The bold elevation which distinguishes the edifices of the French architects, is remarkable in this church, the nave being 90 feet high, and only 39 in width. The workmanship of the buttresses and tracery, is superior to Westminster. The upper range of windows fills up the space between the great arches and the vaulting, and are perfectly similar throughout; they are each 40 feet high, and each divided by four perpendicular mullions, terminated in arches, which support three six foils or roses; the distance between each is three feet. These are superior to any thing at that time in England. The French had introduced the pointed arch before the middle of the 12th, and constructed broad magnificent windows before the middle of the 13th century. This fine structure had fallen into decay in 1802: the vaultings had tumbled in, and the pavement was destroyed.

The crosses erected in 1285, on the road between St Denis and Paris, where Philip III. stopped with the remains of his father Louis, have also been all destroyed. Queen Eleanor, on whose account Edward I. erected crosses, did not die till 1296.

Notre Dame. History.

The church of Notre Dame at Paris, was founded by Childebert in 522, and became the cathedral of the diocese of Paris. Fortunatus says, it anciently had 30 columns, it was destroyed by the Normans, and the present church was founded by Robert the Pious in 1010. At his death it was neglected. Maurice de Sully has the chief merit of the present church. Pope Abu III. laid the first stone; and in 1181 the eastern part was consecrated. Pierre de Nemours, who died 1220, finished the nave and west front; the south was begun in 1257. The building of the chapels continued the greater part of the 14th century; so that the whole was completed in two centuries. The exterior has an excess of ornament in some parts, and a want of it in others. The buttresses are thick, plain, and heavy. The interior is heavy, from a mixture of styles. The body is divided into five aisles, by four ranges of Lombard columns of gross proportions. The Gothic work is without ornament or beauty; and its size alone produces effect. The eastern end is of a triagonal form, and very plain, and it is probably one of the earliest Gothic structures in France. The west front is a striking proof, that the French, at the end of the 12th century, has added great richness to the Gothic, which the English were at least half a century afterwards in producing. The three marigold windows, with their painted glass, are the most magnificent to be met with in any country.

Description.

History. Rheims.

History.

Description.

Comparison with English edifices.

Rheims, the most celebrated cathedral in France, was founded by Ebo in 818. Louis I. granted the walls and gates of the city, and sent his own architect Rumalde to carry on the work. The pediment over the entrance is ornamented with statues of Louis I. Pope Stephen V. and Ebo himself. Some additions were made by Archbishop Hincmar, who dedicated it in 862, in presence of the king. It was burnt on the 6th May 1210, the crypt of Ebo only being left. In the same year the foundation of a new one was laid, and the altar was dedicated 18th Oct. 1215. It was finished in 30 years, that is to say, the body of the church; for the ornaments of the grand façade were put up between that and the English war in 1295. The west front has long been the boast of France. The diminishing or pyramidal form, is more suitable in the Gothic than the square fronts of English cathedrals. It has no mixture of designs; it is rich and light; all that is massy is below, and every thing lightens as it ascends; the architecture is preserved delicate and light, as a relief to the sculpture. The portal is particularly magnificent. In this fine feature the English style is very deficient; even at York, Salisbury, Wells, Litchfield, Westminster, King's College Chapel, &c. In Rheims, the minute beauties are singularly fine; the pinnacles are decorated, and finished with figures, flowers, and crosses; and the fleurs-de-lis spread along the roof, as at Amiens and Abbeville, has a fine effect. The name of the original architect is lost; but Robert de Coucy directed the work during the 13th century. He died in 1311.

Abbey of Nicaise.

Description.

The Abbey of Nicaise at Rheims, was founded by Henry de Braine, Archbishop of Rheims, in 1229. The west end, portal, and front of the nave, were built under Hugh Libergici, who died in 1263. Robert de Coucy was employed to complete it. The transepts must have been left in an unfinished state, also part of the cloisters. These must have been the work that was carrying on from 1322 to 1328, after which nothing more is heard respecting it. This edifice, though not large, is admired for its proportions, lightness, and delicacy of execution, and for its decided Gothic character. Its merits consist more of perforation and relief, than sculptured ornaments. Like Rheims and Amiens, its outline of front is pyramidal; the portal, though small, is prominent and bold, and the rose window over it enriches the façade; the perforation of the towers has a peculiar effect, the unadorned buttresses of which required relief. The whole is decorated with double rows of slender columns on each tower, and the fine arcades with which they are united.

Comparison with English.

The windows and perforations of the work of Hugh Libergici, performed in 1229, have the same width, and mullions were used in England for the first time in Westminster Abbey, but which were at this time unknown in this country. Nicaise had western towers, of which, at that period, there were no instances in England. Rose windows were not equalled here for half a century afterwards. Trefoils, arches in half relief, and opus reticulatum, were then common to churches in both countries.

Amiens.

With regard to the cathedral of Amiens, so remarkable for beauty and lightness, the date is ascertained to correspond nearly with that of Salisbury; they were both begun in the same year, and, in both, the same plan was adhered to throughout: they are, therefore, fair subjects of comparison.

History.

The former cathedrals of Amiens had been consumed by fire. The present edifice was begun in 1220 by Bishop Evrard, and is reported to have been finished under Bertrand d'Abbeville in 1269, but it was not quite completed till 1288. Probably the statues on the west front, the pavement, and fitting-up chapels, might occupy a considerable time after the general parts of the building were finished.

The architects were, 1. Robert Lusarches. } See *Antiquit. of Amiens.*
2. Thomas de Cormont.
3. ——— Reynault.

The foundations of Salisbury cathedral were laid 4th May 1220. The east part, with the first transept, were completed in four years, when the three altars were dedicated by Bishop Poore. The rest of the building was proceeded with during his pontificate; and those of Robert Bingham, and William of York, and the whole was completed in 1258 under Bishop Bridport, when it was dedicated by Boniface, Archbishop of Canterbury, in presence of the king. The external decorations were not finished till two years afterwards. The chapter-house, cloisters, muniment house, &c. were carrying on for ten years afterwards.

Comparison with Salisbury.

The following are the points in which Amiens and Salisbury agree. In the highly pointed arches struck from two centers, and including an equilateral triangle between the imposts and crown of the arch. The lancet windows, and Purbeck marble pillars, very slender and round, encompased by marble. Shafts a little detached, and a profusion of little columns of the same stone in the ornamental parts of the building. The arches or vaultings of the aisles are similar to those of Salisbury and Westminster; the west part is covered with small columns, and the lancet shaped arch is employed to crown the semicircular colonnade at the east end of the choir. The vaulting is like that at Salisbury, high, pitched between the arches and cross springers, without any further decoration.

The following are the points in which Amiens differs from Salisbury.

1. In the disposition of the aisles with the transepts; double aisles on each side of the choir, with the fine semicircular colonnade at the end of it; in the number of columns presented in every point of view.

2. In the proportions, especially the loftiness of the pillars belonging to the arches.

3. In the west front, portal, and display of statuary, in its armies of prophets, martyrs, and angels, which line the doorways, crowd the walls, and swarm round the pinnacles. If Salisbury has the advantage of lightness, it is to be observed, that not lightness but richness was invariably the chief object in this part of the edifice.

4. At Salisbury, Lincoln, and York, the arch buttresses were concealed in the roof of the side aisles, so late as the end of the 12th century. At Amiens, the profusion, of perforations, and decorations, renders them strikingly ornamental.

Chief difference.

5. But the chief difference is in the size and magnificence of the windows. In Salisbury, the long, narrow, sharp-pointed window, generally decorated both inside and outside with small shafts, often combined together and surmounted by a rose, are every where employed. In Amiens there are two tiers of windows, each divided by three perpendicular mullions, surmounted by the same number of roses; those at the east end have five mullions, and are crowned by a pediment, ornamented with a trefoil. Three circular or rose windows enrich the transepts and west front. The whole cathedral is so light, that, excepting the west front, scarcely any wall is visible. Internally there is no row of open arcades between the arches of the naves and upper tier of windows, as in our cathedrals. The whole is much lighter, and more elegant than either Salisbury or Westminster, and proves, that France had made earlier progress in various combinations of Gothic ornaments than England.

Having given the substance of what Mr Whittington has, with so much ingenuity, observed respecting the Gothic architecture of France, we shall now, in the same cursory manner, introduce the sentiments advanced so ably by Dr Milner in favour of England.

Dr Milner.

Dr Milner sets out by stating, that he means to prove, 1. That the whole style of pointed architecture, with all its members, grew by degrees out of the single pointed arch, between the latter end of the 12th and early part of the 14th century. 2. That the pointed arch was discovered from observing intersecting semicircular arches, with which the architects of the latter end of the 12th century decorated their edifices. And, 3. That both these discoveries were made and perfected by the Anglo-Normans and the English.

Establishes three orders.

He establishes three orders in the pointed style, quite as distinct as the Grecian architecture in their several members and proportions; and states, that the essential characteristics consist in the degree of angle of the pointed arch.

1st order at Canterbury.

The *first order*, has very sharp-pointed arches, with pillars and mouldings very heavy and nearly Norman, as found in the east end of Canterbury cathedral, where there is also pillars composed of two three quarter columns united; the plan resembling the figure 8, which is probably the first attempt at clustered columns. Here, as was formerly the general case, the east end was circular, and the bishop's throne and stalls for the clergy, were at the back of the altar, till about the beginning of the 13th century, when the large east windows were introduced in a straight line, and the altars placed under them. Although Gervase was a monk of Canterbury, and an eyewitness of the works carried on, yet, in describing what was done, he never intimates that any part of the style was brought from Syria, Arabia, France, Spain, or Italy, but attributes the merit to the architects employed, both of the name of Williams.

2d Order at York.

The *second order* was employed in York minster. Here the principal columns are divided into clusters, apparently slender, and crowned with historic capitals. From the capitals spring three principal ribs, and two lateral ones, which meet similar ribs from the adjoining columns, and form arches for the magnificent windows of the nave. The mullions continued down to the bottom of their story, form those of the light and uniform triforium gallery; other shafts of the main cluster sustain springers of arches of the intercolumniations, and other springers meeting corresponding ribs from the clusters of the side aisles. The arches are finely shaped, and include equilateral triangles.

3d Order in Henry Seventh's chapel.

The *third order* is exemplified in Henry VII.'s chapel, unrivalled for magnificence, ingenuity, elegance, and delicacy. The pendant capital is its most striking ornament, and the outlines of the arches in intercolumniations are exceedingly obtuse and flat.

First churches inclosed by curtains.

Dr Milner, after describing the churches of Constantine as ancient basilicæ, either imitated or merely inclosed, sometimes by curtains only, and lighted by small round headed or square windows, states, that such were probably the first constructed at York, Lincoln, Rochester, &c. for the Romans were not so much masters of Britain as to build fine structures before their architecture was vitiated. In the course of the 5th century the Ostrogoths and Huns overran Italy; the Visigoths and Suevi, Spain; the Franks and Burgundians, Gaul; and the Saxons, Angles, and Jutes, South Britain. These barbarians destroyed innumerable edifices, but erected none.

Saxon was Roman ill executed.

Roman church at Canterbury.

Wattles.

Wood.

Wilifred glazed the windows of York; he frequently visited Rome; his ornaments found in Italy.

The Saxon architecture was not introduced by the Saxons, but by missionaries from Rome, when they converted the natives at the end of the 6th century; it was Roman, but very rudely executed. They at first made use of a church their ancestors had spared. St Augustine found a church at Canterbury built by the Romans, which was called St Martin's. These missionaries, and the first converts, were at first content to construct them of oaken planks and wattles, and thatch them with reeds. Such a church still exists, or did exist not long ago, at Greenstead in Essex. Paulinus built one at Catarick, which was burnt by the Pagans; he also built one of wood, the mother church of British Christianity, in place of one of wattles and hurdles, and inclosed the whole building with a covering of lead. Wilifred, in the latter part of the 7th century, built Rippon and Hexham, and repaired York, and glazed the windows; but his visits to Rome, his instructions from Archdeacon Boniface, and the Roman workmen he engaged, enabled him to proceed so successfully, and carry his great works to such perfection; even the minute decorations of the Saxon were brought from Rome, but the logs and anchors, caulicolæ and volutes, and all the regular entablatures, had been laid aside before our Saxon ancestors began to build. The incapable workmen rejected all the rich and fine parts; and in imitating the Corinthian capitals, preserved only the stems of the volutes, and introduced animals, &c. The zig zag billet-cable, embattled fret, lozenge, corbel table, may be found in buildings, medals, tesselated pavements, and sepulchres in Italy.

Essendon church doorway Saxon.

No buttresses.

Saxons had towers.

Had bells in 680 A. D.

It is difficult to find original Saxon. The doorway of Essendon church, near Stamford, is known to be Saxon. The portals are generally round headed, with rude carvings in circular parts, while the door itself is of a square form. Saxon edifices are distinguished by their small dimensions, thick walls without buttresses, small windows with round heads without mullions, low cones which cover the towers and flank the corners of the buildings; and also by the rudeness of the workmanship. Mr Bentham is mistaken in saying, that the Saxons did not build high towers till the 10th century, for Richard, prior of Hexham, observes, "that St Mary at Hexham had a tower of a round or cupola form, from which four porticos proceeded; and this resembles Sophia at Constantinople, built about the same time." And Eadmer of Canterbury says, that there were anciently two towers, one over the south and another over the north transepts. So that Mr Bentham was also mistaken in maintaining that the Saxons had no transepts, since both Hexham and Canterbury were in the form of a cross. He also denies that bells were used till the 10th century; but it is clear from Bede, that large bells for assembling congregations were used in 680.

Churches of the Normans built previous to the conquest.

During the 9th and 10th centuries, the Saxons in Britain, and the Franks in Gaul, both then civilized, were as much harassed by new hordes of northern barbarians, as they had, four centuries before, afflicted others. The Danes and Normans overwhelmed and destroyed every thing before them. France, by giving up Normandy, compounded with them, and restored their ecclesiastical edifices with incredible expedition. Robert the Pious, who began to reign in the latter end of the 10th century, built 14 monasteries, and 7 other churches; but even he was outdone by the newly converted Normans in what regarded religion and learning. William I. previous to the invasion of England, built two abbeys in Caen, St Stephen and the Holy Trinity; and his nobles built 38 others, besides what were erected by the prelates. The abbeys of Bec and Caen became the most celebrated school in Europe; most of the prelates who rebuilt the English cathedrals in the latter end of the 11th and beginning of the 12th century, had been educated at one of those places.

Saxon cathedrals demolished and rebuilt.

Dimensions.

Immediately after the conquest they got possession of the great ecclesiastical benefices. Almost all the Saxon cathedrals were demolished, and rebuilt on a larger scale by Mauricius in London, Lanfranc at Canterbury, Thomas at York, Walkelem in Winchester, Gundulph at Rochester, William at Durham, St Wulstan at Worcester, Robert at Hereford, Herbert at Norwich, St Anselm at Chester, and Roger at Sarum. The abbots were not less zealous, the monasteries, as St Augustine at Canterbury, St Albans, Evesham, Glastonbury, Ely, St Edmundsbury, were all rebuilt. Hugh Lupus sent for St Anselm, then prior of Bec, to direct the building the church of the monastery of St Werburgh at Chester. The rage for building became excessive, and led to improvements in an art not confined by rules; the parts mostly remained the same as the Saxon, but the general dimensions were greatly enlarged. The Saxon cathedral of Dunwich was only 120 feet long and 24 wide, (Wilkin's *Archæol.* vol. xii. p. 166.); the celebrated church of Abingdon only 120 feet long; but the Norman cathedrals of York and Lincoln were each 490 feet long; Winchester 500; St Alban's 600; London old St Paul's 690 feet long; and York minster 99 feet. The height of the latter up to the crown of the vault under the beams of the roof, was 102 feet. The buttresses were at first broad, thin, and shelving upwards, without any ornaments, but the workmanship was superior to that of the Saxons. The Norman windows and portals were larger than the Saxon, and supported by pillars at the sides.

Gundulphus visited the holy Land; but he found no pointed arches.

Gundulphus, bishop of Rochester, one of the greatest builders of that age, visited the Holy Land previous to the Crusades; but in none of his works is there one specimen of the pointed architecture to be found. Pocock, Norden, Shaw, Le Brun, found only one church, and that was built in the pointed style in the time of Richard I. by an Englishman. The first crusade began in 1096; Jerusalem was taken in 1099; but no feature of the pointed style was brought from that quarter; neither Exeter, Rochester, or Reading had any in their original works.

No pointed arches in Persia before the 13th centu

In Persia there were no pointed arches earlier than Gengis Khan, in the 13th century. In India there are mausoleums with cinquefoil, but they are of a late date. The temple of Madura is not ancient. The ancient excavations in India, are the same as the primitive style of Egypt, which was also the parent of the Greek. Joseph's Hall in Cairo was built by the rival of Richard I. Saladin, whose name was Jusseff, probably by means of Christian captives after the third crusade. St Sophia, the model of the Turkish mosques, has no pointed arch.

Batalha built by an Irishman.

Bishop Warburton says, that the northern Goths in Spain struck out Gothic architecture in imitation of the groves in which they had formerly worshipped, and executed it by means of Saracenic workmen; but the Goths and Vandals entered Spain in 409; the Moorish Saracens not till 712; and the pointed architecture did not appear till 400 years after. Instead of England drawing instruction in Gothic from the Peninsula, Batalha was built by David Hacket, an Irishman, 200 years after this style had been practised in England. It is only a variety of Winchester and St Stephen's chapel, and not equal to them in sublimity or beauty. The cathedral of Burgos, built in 1221, is more gorgeous but less elegant than Salisbury, and not so magnificent as Lincoln. The specimens from Italy and Sicily, which were produced by Mr Smirke to the Antiquarian Society, have been detected by Sir Harry Englefield to have been additions in times posterior to the original buildings.

Smirke's specimens no evidence.

Dr Milner having proved, that the pointed style was not imported into this country, proceeds to trace its rise and progress in England.

Progress of the Gothic in England.

1. The intersections were at first sometimes only plain semicircles, as in the south transept at Winchester.

2. Resting upon pillars with capitals, or at least an abacus by way of impost, as on the north transept of Durham, the façade of Lincoln; in the latter instance they present a pointed arch with a cusp.

3. By the addition of one or more cusps on each side of the pointed arch, they made a trefoil cinquefoil.

4. By four cusps being introduced into the plain circle, or *oeil de bœuf*, it was converted into a quatrefoil or cross, and by adding more it became a catherine wheel or marigold window. But these did not make their appearance until the beginning of the 13th century.

5. During the latter part of the 12th century, is to be found, as usual, during a change, a mixture, or, as Carter calls it, a struggle between the circular and pointed style. This would not have been the case had the latter been copied from models in Syria, Spain, &c. The first pointed arches, were sometimes obtuse, as in St Cross, but more frequently very acute, as in St Mary Magdalene on the Hill, built in 1174.

6. Pointed arches were used alone before any other feature of that style.

7. The heavy columns were next made into the form of 8, and in ornamental arcades they were very thin and of Purbeck marble, as in the east end of Canterbury cathedral, rebuilt from 1175 to 1180, by William of Sens, and another person also named William Gervase, who knew the old cathedral burnt down in 1174, and was present when the before mentioned repairs were made. He describes the difference which took place in 90 years from its former construction, viz. that the pillars of the new choir were of the same form and thickness, but 12 feet longer than in the old; that the former capitals were plain, and the new delicately carved; that there were no marble columns in the old, but an incredible number in the new; that the stones of the ancient arches were cut with an axe, but those of the new with a chisel; that the vaulting of the side aisles, formerly plain, were now pointed with keystones; that the old was covered with a flat ceiling ornamentally pointed, while the new one was elegantly arched, with hard stone for the ribs and tough stone for the interstices; finally, that there was only one triforium or gallery round the ancient choir, and two in the modern one. Twenty years before the close of the 12th century, no member of Saxon architecture remained in the chancel or choir of Canterbury, except the main arches of the basement story, and certain billet mouldings, which gave way as the work advanced upwards, to the quatrefoil moulding, which very soon became universal, and is a sure criterion of the first order of the pointed style in its most pure state.

8. Canterbury having set the example, others followed as they required repairs. Lincoln in 1195; the choir of Worcester in 1202 to 1218; also the galleries and inside work of Litchfield, and the east end of Winchester, by Godfrey de Lucy, in 1202, were built in the same style, with lancet-shaped arches.

9. Five of these lancet arches placed under one arch, left a space which required to be ornamented with trefoil, quatrefoil, &c. as in the south cross aisle of York, built by Archbishop Walter de Grey in 1227; while the same style was going on at Salisbury, where, on the façade, there is a trefoil at the top of the pediment over pointed arches, and also Purbeck marble columns, with cusped capitals. In the upper story of Salisbury there are three lancet windows placed together, the middle one being raised higher than the others.

10. At this time, the cornice or moulding, which had formerly been attached to the moulding of the arch of the window, was now, by following the including arch, raised much higher than the window arches; it was terminated with a trefoil, but as yet had no crockets.

11. The north transept of Westminster, begun in 1245, (with the exception of the catherine wheel), remains nearly in the same style. Here the windows of the side aisles and upper story are larger and well proportioned, with cinquefoils in their heads; some have a triple cinquefoil under a pointed arch. The arches and windows being placed in rows above each other, led to the idea of the great window with mullions. In the inside of the transept are statues of tolerable workmanship; and on the outside are niches, with pedestals and plain canopies.

Changes in the time Edward I.

1. During the reign of Edward I. (begun 1272) pointed architecture changed its character: The arches, which had been too sharp, became better shaped. They had always one or two cusps on each side of the head, forming trefoils, &c. They had also newly invented mouldings; and the pediments over arches were ornamented with foliage, called Crockets.

2. The pinnacles, which had hitherto been quite plain, were now placed at the side of each arch, on the top of every buttress, and were decorated with crockets, and had a flower on the top, called a Finial. A pinnacle of a larger sort was placed on the great tower, and became a spire, as at Salisbury.

3. The flying buttress, for supporting the upper walls of the nave, which before had been concealed in the roof of the side aisles, was now exposed, and rendered ornamental. The plain niches of the 13th century, were early in the 14th decorated with rich tabernacle filled with statuary.

4. The windows were formed with mullions and transoms, into four, five, six, or sometimes nine bays, and had their heads decorated by tracery and flowers. What favoured the introduction of large west windows, was the abolition of canonical penances, and, of course, penitentiary-porches, in consequence of the frequent crusades.

5. Ribs, in groined ceilings, were no longer simple intersections, but branched into fine tracery, and were tied where they met by a knot, boss, or orb, usually decorated with some device; as in the work at York-minster, early in the 14th century.

6. Pediments, or canopies, which had, during the two first Edwards, risen straight up like an equilateral triangle, began, towards the end of the third Edward, to form a sweeping curve, as may be seen in Winchester College Tower.

Specimens where to be found.

These changes are very evident in Geddington and Waltham Crosses, erected by Edward I.; also in the tomb of Edmund Crouchback, brother of Edward I. in Westminster Abbey: He died in 1296. But the most perfect example is the nave of York-minster, built from 1290 to 1330, and the choir built thirty years after; and St Stephen's Chapel, Westminster, built by Edward III. in 1348; but few vestiges of it remain. Before 1321, the Lady Chapel was added to Lichfield, the whole was groined, and the beautiful western façade constructed; as was also about this time the nave of Westminster.

In 1381, the nave of Canterbury was rebuilt under Courtney and Arundel; and the nave of Winchester was changed by William of Wykeham.

By looking into the roofs of the side aisles of Winchester, or at the west front of Gloucester, St Alban's, and Rumney churches, it may be seen in what manner the circular architecture of the 11th was changed into the pointed of the 14th; and this taste was extended even to parish churches, especially to the windows.

St George's, Windsor, &c.

This pointed style of architecture occupied little more than four centuries. As it acquired its character by being elevated above the semicircle, so its decline commenced by a depression below that standard. This took place in the latter end of the 15th century, of which the most celebrated examples are St George's Chapel at Windsor, built by Edward IV. who died in 1483; King's College Chapel, Cambridge; and Henry Seventh's Chapel, Westminster. The architects were Bishop Cloose and Sir Reginald Bray. The royal chapels and oratories during the reigns of the two last Henry's, are covered with a redundancy of tracery and ornaments of excellent execution, but tiresome from its excess and want of relief. The whole walls of the edifice were converted into a glass frame. The Lady's Chapel at Gloucester is a striking example of this style; but from this false taste must be excepted the cathedral church at Bath, built by Bishop Oliver King in 1500, and the chancel of Winchester, built by Bishop Fox in 1525.

Walls made a mere glass case.

The chief symptoms of the decline of this pointed style, were rendering the walls a mere glass case, depressing the arches, employing a redundancy of tracery ramified into fibres, and loaded at meetings with heavy armorial bearings, badges and releuses, towers covered with hemispherical cupolas, and portals inclosed with square architraves.

Review of the three orders.

1st order.

The first order of the pointed style is to be traced up to Henry I. in 1132, or more certainly to the beginning of Stephen, 1136. It was perfected before the conclusion of the 12th century, and continued till near the conclusion of the 13th century. It is distinguished by its sharp arch, pillars frequently Saxon, but afterwards by detached slender shafts, groining of simply intersecting ribs, plain pediments without crockets or side pinnacles, the windows either without mullions or only having a simple bisecting one, and with a single trefoil or quatrefoil, or other flower, at top. The specimens are the east end of Canterbury, west end of Lincoln, the whole of Salisbury, and the transepts of York and Westminster.

2d order.

The second order reigned from the latter end of the 13th to the middle of the 15th century. Its characteristics are, the finely formed arch, including an equilateral triangle, clustered columns, formed mostly of one stone, elegant and chaste tracery in windows and groins, crocketed pinnacles, tabernacles, and pediments; the latter, towards the end of the 14th century, being formed with a sweep. The specimens are, the nave of Westminster, nave and choir of York, naves of Winchester, Exeter, Canterbury, Wykeham's two colleges, and St Stephen's, Westminster.

3d order.

The third order has been minutely detailed in mentioning the symptoms of decline. It reigned from the latter end of the 15th to nearly the middle of the 16th century. The specimens are, St George's Chapel at Windsor; King's College Chapel, Cambridge; and Henry Seventh's Chapel, Westminster.

General remarks.

Having distinctly traced the progress of the pointed style in England,—having also arranged it into three separate orders, distinguishing the periods in which each was employed, and referred to numerous and splendid specimens now existing,—Dr Milner, with the view of removing some objections and assumptions made by Mr Whittington, concludes with the following remarks:

Remarks.

There is no good reason for alleging, that the intersecting and open pointed arches of St Cross, near Winchester, were not a part of the original structure, but introduced in subsequent alterations and repairs; because,

1. Without the twenty windows, the whole would have been dark at noon-day.

2. The cornice from which the pointed arches spring goes quite through the wall, and is evidently a part of the structure.

3. The pointed arches in the south transept are the same as the windows, both in regard to design and workmanship.

The primary object of the inventors of pointed architecture being to excite devotion and awe, for this purpose they studied sublimity rather than richness: Hence the portals of Amiens and Rheims are, notwithstanding the armies of saints, prophets, martyrs, and angels, inferior to those of York and Litchfield. Admitting the French taste, the façade of walls would be the most beautiful of our English cathedrals. But the same false taste prevails in producing Amiens as a model of perfection, on account of having the appearance of being all windows; and Dr Milner produces the choir of Lincoln and nave of York as superior to the same parts in the boasted cathedrals of Beauvais and Amiens.

Conclusion.

Having impartially sketched out the views taken by these well informed men, of the rise and progress of Gothic architecture in France and England, the reader will form his own judgment respecting the claims of the two countries. We shall probably be not far from the truth in admitting, that the advantages were mutual, and that benefits alternately flowed from the operations on each side of the channel. That the French and Normans had, earlier than the Saxons in England, erected splendid ecclesiastical edifices, must be admitted; and that the English did not acquire information from examining the French works, during the wars they carried on in that country, is improbable; but, on the other hand, as England was tranquil while France was harassed during the 14th and 15th centuries, it is admitted, even by Mr Whittington, that the former country was, from that circumstance, enabled to carry Gothic architecture to a greater degree of perfection than the former; and without disputing as to the mere discovery of the first, or exclusive claim to the latter, the regular steps so distinctly traced by Dr Milner, seem to secure to England the merit of forming, and practising most extensively, the second or most perfect order of the pointed style.

This Gothic school is not more remarkable for the elegance of its forms, than the scientific skill with which the essential parts are adjusted. The small quantity of materials employed in edifices of great extent and elevation, when compared to similar Greek and Roman works, resemble films of net work, or slight frames of timber or iron. To construct edifices of this description, with small sand stones, so as to be stable and lasting, far surpasses the efforts of ancient artists, whose trust was reposed in the hardness and magnitude of their materials. In Gothic construction, all depended upon the correct adjustment of the bearings and thrusts of the different arches operating in various directions; not opposed by thick walls, but balanced by each other, and by buttresses and pinnacles, apparently only objects of decoration.

The Greek architects having no arches, had only to

Comparison of the Greek and Gothic.

arrange perpendicular pressures, and the strength of lintels from pillar to pillar, and for this their fine marble quarries afforded a material which removed all difficulties. They had, it is true, the principle of arches in the construction of their timber roofs; but this was rendered an easy task, by introducing ranges of pillars in the inside of the cells. The architect, therefore, instead of studying the principles of geometrical construction, directed his whole attention to that magnificence, which consisted in the magnitude and masterly execution of columns and sculptures.

Pinnacle and spire.

Conjecture concerning their origin.

The outlines of the Greek architecture, excepting the roof, were all horizontal or perpendicular; those of the Gothic were perpendicular, or tapering upwards, as the pointed arch, the pinnacle, or spire; and those were generally constructed with stones of very small dimensions. In the spire of Salisbury, which (besides the tower) is 180 feet high, the walls are only seven inches thick. It is not improbable, that this pyramidal form was brought from the East or from Egypt, or copied from some Roman remains; as there are instances, besides the Egyptian pyramids and beautiful obelisks, of the Romans finishing their mausoleums or sepulchres with a small pyramid. There is one of this shape near Terracina, on the confines of the ecclesiastical state, on the side of the highway leading to Naples. It was discovered by Perro Ligorio in 1573. It seemed to him fully as old as the Appian way, to which it was adjoining. *Parallel of the Ancient Architecture with the Modern*, by Rowland Freart.

Spires at Salisbury, Grantham, Coventry.

These spires, one of the most striking features in Gothic architecture, are, in their purest and most perfect forms, peculiar to England. The finest are those which are lofty, contained within small angles, and which have not their outlines broken by any ornament. In different parts of England there are many very beautiful spires; but the most lofty are those at Salisbury, Grantham, and Coventry.

Revival of Roman Architecture.

Roman [illegible]

Buscheto.

Brunileschi.

Plate CLXXIII.

While, during the latter part of the 15th and beginning of the 16th century, the ornamental Gothic was carried to luxuriant extravagance in England, the ancient Roman architecture began to occupy the attention of men of talents in Italy. In 1016, Buscheto, a Greek of the island of Dulichio, constructed the cathedral of Pisa with marble columns and a dome. He had many disciples, and was reckoned the founder of modern architecture in Europe. Early in the 15th century, Filippo Brunileschi, a Florentine, born in 1377, whose ardent and original mind led him to study, and form his taste from the remains of ancient buildings at Rome, undertook and completed the cathedral of Florence with an octagonal cupola of great dimensions, which a convocation of the architects of that age (1420) had pronounced impracticable. (See Plate CLXXIII.) The completion of this edifice, the example of the other excellent works in which he was employed, and the perusal of the writings of Vitruvius, created a general disposition to this style of architecture. This was increased by the treatise *De Re Ædificatoria*, which was shortly after published by Leon

Alberti.

Battista Alberti, a learned canon of the metropolitan church of Florence, born in 1398, who also practised architecture. His principal performance is reckoned the new works and embellishments of the church of St Francis at Rimini. These circumstances were preparatory to the great undertaking which fixed the epoch of the revival, and gave to the Christian world a temple, which, in magnitude and variety of parts, far surpassed every Grecian and Roman work of a similar description. Under

Bramante.

Plate CLXXIV.

Architects of St Peter's.

Vignola.

Julius II. Bramante, a native of the duchy of Urbino, born in 1444, having been distinguished by his talents in various architectural works at Rome, under Pope Alexander VI. was employed first to design the great theatre between the old Vatican and Belvidere, and afterwards the plan for St Peter's church; (See Plate CLXXIV.) and that magnificent structure was carried on under the direction of Raphael de Urbino, the friend, some say the relation, of Bramante. Baldasse Poruzzi, Frater Johannus Jocundus, Antonio Sangallo, Michael Angelo, Buonarroti, Guilio Romano, and Giacomo Barozzi, known by the name of Vignola, from a place in the Modenese, where he was born in 1507,—these eminent men planned and conducted many churches and palaces; and Vignola, from his elaborate publications, and fruitful yet sober invention, has been not improperly styled the legislator of architecture.

Palladio.

His works.

Plate CLXXVII.

During the pontificate of Leo X. architecture, sculpture, and painting, were greatly encouraged. Andrea Palladio, born at Vicenza 1508; Sebastian Serlio, who flourished in Lombardy about 1530; and Vicenza Scamozzi, born at Vicenza in 1552, all cultivated the ancient style with great success; more especially Palladio, whose unwearied and faithful labours in examining the remains of ancient structures, combined with the taste and skill with which he transfused their style into the numerous edifices for which he was architect, and his able treatise published in 1570, have obtained for him the title of the restorer of Roman architecture. The reputation which he early acquired, afforded him numerous opportunities of constructing works of various descriptions, and of great magnificence. Of these, the theatre at Vicenza, and the Villa Capra, or Rotunda, (see Plate CLXXVII.) are fine specimens of his genius and skill, and justify his title to the appellation of the Raphael of Italian architects.

France.

Church of the Invalids by Mansart.

St Genevieve by Soufflet.

Perraul builds t south fro of the Louvre.

Versailles.

British Museum.

Plate CLXXXI.

France was not hasty in adopting the Roman manner as revived in Italy. It was not till the 17th century, that St Louis de la Rue St Antoine was constructed from a design executed at Rome by Vignola, the front and cupola of the Invalids by Mansart, and St Genevieve, (now the pantheon,) with its magnificent portico, by Soufflet, are reckoned the best specimens. The south-east front of the old Louvre by Claude Perrault, consisting of a colonnade of the Corinthian order 400 feet in length, possesses great simplicity, and produces a noble effect. The gallery of the Thuilleries 1300 feet in length, is uncommon and striking. The observatory is grand and imposing; and the fountain Grenelle is very beautiful. The palace at Versailles is more remarkable for its magnitude than good taste; there is a great monotony in it, and the ornaments are trifling and crowded. The British museum, built upon the model of French palaces, by Monsieur Pouget, is an evidence, that the roof is much too predominating a feature. See Plate CLXXXI.

Fischers.

In Germany, this Roman style made no progress. Even at Vienna, in the church of St Charles Borromeo, the best work of John Bernard Fischers, there is little merit. In the church of the imperial convent at Molck in Austria, he has been more successful. See Dallaway, *Observ.*

Holbein in England.

Towards the middle of the 16th century, and near the close of the reign of Henry the VIII. Holbein introduced Roman architecture into England; but his labours did not extend beyond porticos and portals. St James's palace in Westminster, opposite to Whitehall, and Wilton house, contained specimens of his works.

John of Padua.

After him, John of Padua built the palace of the Protector Somerset on the bank of the river Thames,

Longleat.
PLATE CLXXVIII.

Castle Ashly.
Coleshill.

between the cities of London and Westminster. He also built Longleat in Wiltshire, wherein are introduced the Doric, Ionic, and Corinthian orders immediately over each other, which formed a very regular and magnificent edifice, (See Plate CLXXVIII.) But it was not until the beginning of the 17th century, that the practice of this style was completely established by Inigo Jones. He was born in London in 1572, and having early shewn a strong disposition for drawing, he was, by the munificence of the Earl of Pembroke, enabled to travel through Italy. Here the remains of the ancient edifices, the magnificent works of modern architecture at Rome, but above all those of Palladio, afforded a field for study, upon which he entered with ardour, and benefited to such a degree, as to enable him to become the Palladio of his native country. From Rome he went to Denmark, at the request of Christian IV. where he was found by James I. and was brought over to Scotland by Queen Anne. Here he altered and improved the old palace of Holyrood House, and afterwards gave designs for Heriot's hospital, and probably the parliament house. In 1612 he returned to Italy, and finished his studies. Of his early and least classical style, the inner quadrangle of St John's college, Oxford, is a specimen. Here the arches rest immediately upon the capitals of the columns. There are busts between the arches, and heavy wreaths of foliage in the alcoves. But he afterwards composed, with simplicity and great classical elegance, the banqueting house Whitehall, Greenwich Hospital, Surgeon's Hall, and Covent Garden church. Besides these public works, Wilton house, the south and east side of Castle Ashley, Lord Radnor's at Coleshill in Berkshire, and Stoke Park in Northamptonshire, are known to be his. But his practice having been very extensive, many other edifices are in part his, and formed upon his models. So that, besides the classical elegance which he introduced into public buildings, we are equally indebted to him for the convenience and comfort enjoyed in the private dwellings which he planned.

Chris-[illegible]

Next in succession to Inigo Jones, is Sir Christopher Wren. He was eminently possessed of the qualifications requisite for a perfect architect; his education was liberal; he was one of the first geometricians of the age in which he lived; he had a disposition for mechanics; he possessed a dispassionate but persevering temper, and had a fine taste.

St Paul's.
PLATE CLXXIV.

We have heard of few architects, either ancient or modern, in whom all these requisites were so perfectly united. He was of Wadham college Oxford, and became Savilian professor of astronomy in that university. Having given various excellent specimens of his architectural talents in that beautiful city, he was appointed a commissioner for repairing St Paul's church in London. In 1665, he travelled into France, to examine the public buildings of that nation. After the great fire of 1666, he was fixed upon to form the plan, and direct the rebuilding of St Paul's. This he accomplished in the course of 35 years, and has produced an edifice, of which his country has reason to be proud. (See Plate CLXXIV.) The extreme length is 530 feet, breadth 250, height 366, breadth of façade 180, outward diameter of the cupola 140, inward at whispering gallery 112 feet. The original and favourite design of the architect was not adopted by the commissioners. It, in many respects, possessed more magnificent features than the present. Instead of two it consisted of one order only, and the portico was very considerably insulated. Every part had by this means much more simplicity, elevation, and boldness, and there being only a single range of large windows, it conveyed the idea of one great apartment. Internally, the dome rested upon the entablature of the order, without the intervention of arches. Plates of this design have been published, and a model of it is still preserved in an apartment of the present edifice.

St Stephen's, Walbrook.
PLATE CLXXV.
St Mary le Bow.
Monument.

The devastation caused by the great fire of 1666, afforded many other opportunities for his architectural talents. In the church of St Stephen's, Walbrook, there is a most perfect specimen of his skill, (see Plate CLXXV.) It consists internally of a cupola, resting upon Corinthian columns; the whole distributed and adjusted with the utmost delicacy and correctness. Many of the other churches of the city owe their most distinguishing features to his masterly hand. The tower of St Mary le Bow is a singular and bold ornament for a great city. In the monument, he has constructed a column equal in design and execution, and superior in elevation, to any of antiquity: if his material is inferior, or the sculptures less numerous, prudence and necessity limited his exertions. The height of this column is 202 feet; that of Antonine, at Rome, was 175; and that of Trajan only 147.

Greenwich hospital.

The other works of this great architect are numerous. The parts he planned in Greenwich Hospital are inferior to few edifices, ancient or modern. The colonnades, of 347 feet in length, will bear a comparison with those of Bernini, in front of St Peter's.

Trinity college Cambridge.

Chelsea Hospital, and the modern part of Hampton Court, though chiefly of brick, are yet magnificent buildings. And the garden front and chapel of Trinity College, Cambridge; the Ashmolean Museum, and Sheldonian Theatre, at Oxford, besides many lesser works, will perpetuate his fame in that singularly fine city.

Gibbs.
St Martin's in the Fields.
Radcliffe library.

In the works of Sir C. Wren, the Roman manner was completely established; the Gothic was totally rejected, and branded with terms of contempt. The public buildings were afterwards all designed in this newly adopted style; and, for some time, Gibbs appears to have been most extensively employed in the management of many of them. He was a scrupulous copyist of Palladio, but he seldom displayed good taste. In the London churches, of St Martin's in the Fields, the New Church in the Strand, and St George's, Hanover Square, he had ample opportunities of displaying talents; but it is only in St Martin's that any degree of merit can be allowed him: there the single Corinthian order, carried up the whole height, and quite around the church, is simple and correct; and the portico is the only one in London, which conveys any idea of that of the pantheon at Rome; but the two rows of rusticated windows destroy simplicity, and greatly injure the general appearance. The portico of St George's, Hanover Square, wants depth; and the New Church in the Strand is frittered into trifling parts, and covered with tawdry ornaments. In the Radcliffe Library, at Oxford, there is much to blame; the cupola seems to have sunk from its intended situation, and the doors and windows are in a worse style than those of St Martin's. So completely was the Gothic style by this time supplanted by the Palladian, that Gibbs attached a church, designed in the latter style, to a very fine Gothic tower, in the town of Derby. He published a volume of designs in 1728.

Sir John Vanburgh.
Blenheim house.
PLATE CLXXIX.

About the same time with Gibbs, Sir John Vanburgh practised architecture extensively in England; but although the works he executed were all palaces and for nobles, yet, being for private persons, it is Blenheim alone which can be admitted in the list of public edifices. The style of this splendid palace, (see Plate CLXXIX.) erected at the public expence early in the 18th century, displays much boldness and originality of genius. The diversity and novelty of the outlines, both in the plan and elevation, form a strong contrast with the tameness of other buildings. The whole façade has more the appearance of a triumphal monument, than a private dwelling. His poetical mind, independent of previous canons, imagined forms expressive of the character he had assumed; and certainly, in what regards general outlines, and the disposition of the principal members, few architectural works have so completely succeeded; but in the subordinate features, his taste has been grossly deficient; and it is difficult to conceive, how talents like his could admit the rude clumsiness which but too frequently deforms his buildings. The central front of Blenheim is scarcely a sufficient mass for the wings.

Sir W. Chambers.

In the conduct of great public works, the next architect was Sir William Chambers. He has displayed a strong disposition to investigate subjects connected with architecture. He took much pains to acquire a knowledge of the Chinese mode of building and gardening. On this subject he published a treatise, and produced specimens in the king's gardens at Kew. He bestowed still more attention upon the Roman style; and, in his Treatise on Civil Architecture, he has, with great care, made a judicious selection from the purest remains of antiquity in Italy, and from the works of its ablest restorers. He was so totally ignorant of Greek architecture, as to dispute its being carried to much perfection, or practised on a large scale by that people. His situation, as surveyor-general of the board of works, led him to be employed in edifices, where there was abundant opportunities of displaying his talents.

Somerset Place.

The square of Somerset Place is entirely from his designs, and executed under his direction. Its situation on the banks of the Thames is favourable, for being viewed from the middle of the river, or Westminster Bridge. Towards the street, the front, which is on a line with the houses on each side of it, is seen to disadvantage. The inside of the square has all the advantages a similar space can afford. The whole design has not been completed, but the central part has; and we therefore see what must have been intended as the principal features of the composition. In the river front, there is a fine terrace; but the extensive façade, which is elevated upon it, is deficient in majesty. The disproportioned height of the basement takes away from the effect of the order. In the dark recesses, the columns appear very diminutive. If the basement had been only so high above the terrace, as to raise the order to be all seen from the middle of the river, the parts would have been more distinct and impressive; and had the face of the building been plain, instead of being wholly cut into small rustics, there would have been more simplicity. The dome in the centre of the roof is much too small. The small extent of the street front renders the improper height of the basement more conspicuous; and the whole is rather crowded than grand. Within the square, which is 300 feet north and south, and 200 east and west, there is a tiresome repetition of rustic work: there are many fine door-cases and windows, and much exquisite sculpture; but as a great design, it is deficient in the magnificence which a national edifice of this description ought to possess. The interior of the building is arranged with much care; and it has several fine staircases. This architect appears to have been careful and persevering, and endeavouring correctly to follow what he conceived the true classical style; but he was ignorant of, or despised Greek architecture, and seems to have been deficient in original genius and taste. He died in 1796.

Adam.

About this time, Robert Adam also rose to much eminence as an architect: in many respects, he appears to have been the reverse of Sir William Chambers. He early travelled into Italy; and probably from a desire of distinguishing himself, by introducing a subject untouched by former students, he, with much assiduity and care, made accurate measurements and drawings of the once splendid palace of the Emperor Dioclesian, at Spalatro in Dalmatia: these he published, with finely engraved plates, in one folio volume in 1764. He designed the buildings called the Adelphi, and, in conjunction with his two brothers, conducted the erection of them; although composing a series of private houses, yet as a piece of street architecture, or façade to the river, the Adelphi becomes a public building.

Adelphi.

From the river the effect is very imposing. Economy rendered it necessary to build with brick, instead of Portland stone, and to make the ornamental parts of a composition which he invented. Being of less extent than Somerset House, it acquires more apparent elevation and lightness. The outlines of the tall pilasters, in the centre building and wings, add very much to this effect, while the long horizontal lines of light frieze and cornice preserve great simplicity; but perhaps the most striking feature is, the appearance of the whole mass standing upon the dark caverns, formed by arcades under the terrace, and the arched passages which lead from the wharfs on the shore up to the street called the Strand. The desire of converting as much as possible of the space into buildings, has made the streets of the Adelphi too narrow. This is both inconvenient and unpleasant. Towards the Strand the architecture is disfigured by circles, and a profusion of unnecessary and minute ornaments. In this instance, as well as in many of his designs for individuals, it appears, that his fertile mind had been unfortunately too strongly infected by the luxuriant, but depraved style of Dioclesian's palace. The Register Office at Edinburgh will be noticed in the Architecture of Scotland; and his other numerous and masterly works will be noticed under the Section of DOMESTIC ARCHITECTURE and that of SCOTLAND. He died in 1792.

But previous to the publication of Mr Adam's drawings, England had been instructed and astonished by the most splendid phenomenon which the Roman school ever exhibited: We here refer to the ruins of Palmyra and Balbec, which Messrs Dawkins and Wood visited in 1751, and published descriptions of in 1753 and 1757. The particulars respecting the architecture of these extraordinary edifices, will be presented in considerable detail under the head of Practice; but we consider it only as justice to the memory of Mr Dawkin's, here to observe,

Mr Dawkin's munificence.

that the whole expence attending the journey, draftsmen, engravers, and publications, was defrayed by him, without any view of participation in the returns made by the publications, which were very considerable, but which he generously assigned to his colleague Mr Wood: And, what is perhaps equally deserving of admiration, was his indefatigable attention to the measurements on the spot, and afterwards to their being accurately represented in the engravings; to the truth of which the writer of this article is enabled to bear witness, by the kindness of his nephew James Dawkins, Esq. M. P. in whose possession the beautiful original drawings now are; and who, with his uncle's liberality of disposition, inherits his taste for the fine arts. From that gentleman we also learn, that Britain had nearly been deprived of these architectural treasures, by the Italian architect who had been employed as a draftsman. This person, though inimitably expert as an artist, was so unprincipled as to abscond with all

Situation of Palmyra.

History.

the finished drawings. By immediate and active pursuit, those relating to the architectural parts were all recovered; but twenty-six finely executed landscapes in Egypt, Greece, and Asia Minor, were, only a few years ago, accidentally discovered and purchased by the present Mr Dawkins, in a public auction room in London. From the publications of Messrs Dawkins and Wood, we learn, that Palmyra is situated in the middle of a sandy desart, 203 miles from the Mediterranean, 176 from Damascus, and 333 from Seleucia: That it had risen to great splendour in the time of Zenobia, when it was taken and much injured by the Roman emperor Aurelian, who ordered Ceionius Bassus to repair the temple of the Sun, with the value of the gold and jewels found in Zenobia's possession. It appears by an inscription copied by our travellers, that Dioclesian erected a considerable edifice at Palmyra, under the charge of Hierocles; but that no inscription was discovered older than the Christian æra, nor any later than Justinian; that the eldest have Palmyrean names, and the latter Roman prænomina; that, with the exception of two Ionic semi-columns at each end of the cell of the temple of the Sun, and two in one mausoleum, the whole of the architecture has been of the Corinthian order, highly decorated; and that, with the exception of four granite pillars in the middle of the long portico, the whole was composed of white marble.

Balbec.

The temple of the Sun at Balbec, of uncommon magnitude and splendour, appears to have been built under that excellent Roman emperor Ælius Antoninus Pius, near Libanus in Phœnicia, at a resting place between Tyre and Palmyra.

Messrs Stuart and Revet.

Ionian Antiquities.

Greenwich chapel.

It was a singular circumstance, that, until the time of Messrs Stuart and Revet in 1751, there had been no recourse to the school from whence the Romans derived all their knowledge of architecture. The indefatigable and faithful labours of these deserving artists, who were also supported chiefly by the munificence of Mr Dawkins, furnished correct plans and profiles of many magnificent and beautiful remains in Attica, and other parts of Greece. This undertaking occupied four years, during three of which they resided chiefly in Athens. Nothing can exceed the accuracy of their measurements and delineations; and their work put England for the first time in possession of Grecian architecture. By comparing these specimens with those copied from the best Roman works, it is evident how much architecture had suffered in the hands of the rude conquerors of the world. The correct simplicity, bold features, and delicate proportions of the Greek architecture, display the superiority of genius and taste of that extraordinary people. Stuart's Antiquities of Athens was followed by a similar work upon those of Ionia, delineated with equal judgment and care by Messrs Revet and Pars, who returned in 1766 from a journey made by the direction and at the expence of the Dilettanti Society, and which has secured to us the taste and manner of the refined inhabitants of Ionia. These works, and the buildings erected under the direction of Mr Stuart, have produced a considerable change in the architecture of this country. The restoration of the chapel of Greenwich Hospital, is a fine display of the application of the Greek style.

Wyatt.

Pantheon, Oxford Street.

Oriel College, Oxford.

Gateway. Canterbury Court, Oxford.

After the introduction of pure Greek architecture, it has been fortunate that an architect (Mr Wyatt) has risen to eminence, whose taste exceeds in correctness that of his predecessors. The work which at once displayed his talents, and introduced him to extensive employment, the Pantheon, falls under the head of those for public amusements. In the front of the library of Oriel college in Oxford, he has given a correct Ionic; but even here the basement is too high for the order it supports, and the ornamental superstructure is too evidently restricted to the front only. It is a fine screen set up against a building, of which it does not appear to form a component part, which it might have been rendered, by employing a pilaster instead of a column, and break at each extremity. His Doric gateway to Canterbury court, though not purely Greek, is a fine instance of the beautiful simplicity of that order. When compared to the Greek, the columns appear too slender, and the alternate square and circular tablets, recesses, and niches, do but imperfectly harmonize with the gravity of the Doric. Mr Wyatt has been very extensively employed in repairing and restoring many Gothic cathedrals, although he has been, in some instances, accused of not being sufficiently correct in keeping distinct the different orders of this school. He has, in general, succeeded admirably well in preserving the spirit of the originals. The public are much indebted to him, not only for what he has himself performed, but for proving, that these fine structures may be preserved to posterity.

Legislation.

Edifices for the purposes of legislation.

Court of Westminster.

St Stephen's Chapel.

Buildings for the purposes of legislation and the distribution of justice, in the time of the Greeks and Romans, were known by the name of the forum and basilicæ. In England, they are distinguished by the names of senate-house, courts of justice, jails, and bridewells. The national senate-house of these kingdoms is situated in the old palace of Westminster, erected by Edward the Confessor, to which William Rufus added the great hall as an appendage. The hall was rebuilt by Richard II. in 1397, and is 270 feet in length, and 74 in breadth. The apartment called the House of Commons was originally a chapel built by king Stephen, and dedicated to St Stephen the martyr. It was rebuilt by Edward III. in 1347. There is little architectural merit in those edifices, yet, notwithstanding this, the features of antiquity which every way present themselves, associated with the scenes they have witnessed, create a solemnity, and inspire a respect, which more modern and regular architecture would probably fail to command. The courts of justice, though apparently confined, and externally fitted up with bad taste, derive much dignity from the magnificent hall in which they are placed, and it also affords much real conveniency to the concourse of people, whom business frequently obliges to attend upon the courts. It answers the same purposes as the extensive porticos of the Greeks and Romans, and is much more suitable to this climate.

Guildhall.

Newgate.

In the city of London, excepting the great apartment of Guildhall, which is 155 feet long, 42 broad, and 55 high, and the façade of the building by Mr Dance, all that is connected with the courts is disgracefully mean and inconvenient. The prison of Newgate is, in external appearance, a specimen of architecture well adapted to its purposes; but there are several ornaments sunk into recesses in the rough rustic façade, which might be spared.

Provincial courts of justice, &c.

In many counties of England, much attention has been paid to the construction of courts of justice, jails, and bridewells. In some of them, a very considerable degree of architectural skill has been displayed. The most perfect are those, where the situation and other circumstances admit of their being constructed adjacent to, and so as to communicate with each other, yet are partially accessible, and have a sufficiency of light and air. In many parts of England these buildings, although cir-

John Howard.

cumstances did not admit of their being immediately connected, are yet each of them excellent. It has been chiefly owing to the unwearied exertions of the benevolent John Howard, that so speedy and effectual a renovation of the jails and bridewells has taken place. So far as regards the buildings, his leading principles were, providing accommodation for different classes of prisoners, having separate sleeping cells, also opportunity for solitary confinement, with sufficient ventilation, plentiful supplies of water, and the means of complete inspection. These general principles appear applicable to all countries, and if judiciously employed, greatly ameliorate the situation of the prisoner, accomplishing at the same time, all that is requisite for the purposes of security, punishment, and reformation.

Mansion house, London.

The mansion-house of London, forming the residence, and containing the court of the first magistrate of a city, which for population, wealth, enterprise, accommodation, and perfect arrangement, has seldom if ever been equalled, falls with propriety under this head. Its portico is bold and striking, and, though some of its features are sufficiently clumsy, yet, as a whole, it is grand and impressive, and reflects credit upon its architect, the father and predecessor in office of the present ingenious city architect Mr Dance. It has been reproached with heaviness; but we should be sorry to commit its renovation into the hands of such architects as designed the Bank. It was begun in 1739, and completed in 1753.

India house.

As the hall and office of the managers of the affairs of an extensive, populous, and rich empire, the India house falls also under the description of an edifice for the purposes of legislation. Its north front possesses more chastity of design, than most public buildings of modern construction. There is no break in it excepting that made by a very fine portico, consisting of six Ionic columns, occupying the whole height of the structure, and ornamented with excellent sculpture by the hand of Bacon. Had the upper row of windows been of greater size, they would have added to the dignity of the building, and lessened the space of dead wall which is over them; as it is, having only a range of light level cornices, and the face of the wall being quite plain, the effect is good.

Public Exercises and Amusements.

Public exercises and amusements.

Amongst the Greeks and Romans, their exercises and amusements had their origin chiefly in the preparation of their youth for the modes of combat which were then practised, and in the general interest taken by the rest of the people in the performances of their children and relations. These early grew into habits, and of course became a gratification. Legislators perceived their importance, and determined their order by fixed regulations. We are informed, that the first gymnasium was found amongst the severe Spartans. They were afterwards established in every district of Greece. The Olympic games became the general rendezvous, and common bond of union amongst all the states of Greece. At Rome, the games of the circus were said to have been instituted by Evander, and re-established by Romulus in an island of the Tiber. Both Greece and Rome had the additions of theatres. Amongst the Romans, these edifices were expanded to a prodigious capacity, and, in the hands of artful and worthless men, became the means of debauching the degenerate offspring of that once simple and irresistible people.

Theatre.

In modern times, the mode of warfare being so completely changed, as to render superiority of mind of more consequence than the mere athletic force of body, the exercises which were calculated chiefly for the improvement of the latter, have long ago ceased to be in estimation to demand purpose establishments. The amusements of the theatre have, however, been carried to a degree of refinement unknown to the ancients, and, in an architectural point of view, have become sufficiently important to require a separate article. The amusements of the ancients cannot, with propriety, be separated from those of the moderns; so that we must, for further information, refer our readers to the article THEATRE, under which the several edifices adapted to these purposes will be noticed at considerable length.

Domestic Architecture.

Domestic architecture.

General observations.

In considering the art of building, as adapted to the purposes of domestic life, it is necessary to advert not only to the climate, and general manners, but also to the several gradations of society in which individuals are placed. In England, we have the prince, the noble, the smaller land-owner, the freeholder, the cottager, the merchant, manufacturer, and mechanic, and others who are engaged in the church, physic, and law. But the peculiarities which arise from public offices, or from different professions or occupations, must be treated of under separate heads; here we can only regard the accommodation of their families.

Chinese.

In external appearance, internal arrangement, and also decoration, the dwelling of the prince ought to be suitable to his superior situation; the habitation of the noble will also be in some measure modelled by his rank and duties; and that of others, as their possession of wealth enables them to enjoy profusion, or confines them to the mere necessaries of life. National habits and manners also, greatly affect the domestic architecture of a country. In China, where there is no hereditary rank, there is little appearance of distinction in their houses, excepting in the dwellings of public officers; and the houses of those officers, and even the palaces of the emperor, are insignificant, when compared with the extent and riches of the empire. Amongst the Greeks, while the utmost efforts of fine architecture were exerted upon temples and other public edifices, the private dwellings were generally plain and mean. Yet from the plan of a Greek villa given by Palladio from Vitruvius, (see Plate CLXI.) it appears that a considerable degree of magnificence had at last been introduced; but we have no account of the period when this change took place.

Greeks. PLATE CLXI.

Romans.

Until near the termination of the Roman republic, the utmost simplicity was preserved both in their public buildings and private dwellings; but immediately on the influx of Asiatic wealth, both were carried to an extreme of magnificence. The tribute and plunder of the extensive provinces centering in Italy, the villas of the principal Romans, much exceeded in number, extent, and splendour, all others in the world. The plan given by Vitruvius, (see Plate CLXI.) will convey an idea of their arrangement, and shew, that the palaces of modern princes will suffer by being compared with them.

PLATE CLXI.

This unbounded luxury being created and supported by the tribute and plunder of the richest provinces of the empire, could only exist while these were kept in subjection, or were ruined, and they were accordingly in the end totally destroyed with their degenerate possessors, by the different barbarous hordes which overwhelmed the empire.

Goths, Vandals.

For many ages after the destruction of the Roman empire by the Goths, Vandals, and Mahometan Arabs, the private dwellings of the conquerors were extremely mean: being scarcely advanced beyond the shepherd state, they set little value upon fixed habitations. It

Baron's castle.

was not until the whole of Europe was overrun, and the various tribes had settled upon and begun to cultivate different districts, that permanent habitations became an object of attention. The feuds between neighbouring tribes, and the attempts of fresh swarms to dispossess those already settled and partly civilized, led to the construction of places of strength; and these were contrived, not only to lodge the chief and his immediate dependants, but also to afford protection for cattle and effects in cases of violent attack. The forms of the earliest being very little calculated for domestic purposes, were probably at first only resorted to occasionally, but they in time became the never-failing appendages of every great lordship, and the constant habitation of the baron's family.

Britain.

In Britain, the Saxons most probably preserved and made use of fortresses which had been constructed by the Romans; and it is certain, that King Alfred, after having expelled the Danes, caused many towers to be erected: But it was the Norman conquest which completely covered England with fortified castles upon an improved plan.

Norman fortress.

Rochester castle.

The leading features of a Norman fortress, were a lofty mound of earth encompassed by a very deep ditch. From the summit of the mound rose either a square tower of several stories, or a circular one, which was lower, and of greater diameter. They were usually approached by means of very steep stone stairs on the outside. Other material parts were, the gateway or entrance tower, and the barbican or watch-tower, both of which had a communication with the keep. Most of the keeps had four stories. In the souterain, vaulted with stone, the military engines and stores were deposited. In the walls were placed the winding staircase, the well for water, the large oven, inclosed galleries and chimnies, with an aperture open to the sky, which communicated to the donjon all the light and air it enjoyed: There was also a flue, not more than eight inches diameter, for conveying sound to every part. The state apartment occupied the whole of the third story; and the staircases leading to it were commodious, and sometimes sufficiently large to admit of military engines. Adjoining the great chamber was an oratory, lighted by a large window. At Rochester Castle, in the ground-floor, there was no light, loop-holes only were allowed in the second, but in the third were three large round-headed arched windows, placed so high as not to be looked through, and so defended by an internal arcade, that no missile weapon could enter or fall with effect. Each floor had communication with the well. The chimnies were capacious, and projected into the room, resting upon small pillars; and the sinks were contrived in an oblique direction, so that no weapon could enter through them.

Gundulph.

Gundulph, bishop of Rochester, was the most eminent castle architect after the conquest. In the Towers of London and Rochester he left models of that sort of architecture. During the reign of Henry II. additions were made to the second ballium, the barbican, and entrance tower; and in these the baron and his family usually resided, having recourse to the keep only during a siege.

Castles under Edward I.

Conway.

Caernarvon.

More extended and improved plans were introduced by Edward I. on his return from the crusade, after having seen the castles and fortified cities of the Levant and Holy Land. Conway, in North Wales, affords an example of a fortified town, castle, and palace, being imitated. Caernarvon of a castle and palace only. Edward III. having rendered Windsor a magnificent habitation, was imitated by many of his barons; and, during the contentions of the houses of York and Lancaster, these fortified dwellings were rendered peculiarly grand, by the projecting turrets which were placed at the salient angles, and the hanging galleries which were constructed over the gateways. These castles and their outworks frequently occupied several acres of ground. The court was very spacious; and the halls and state chambers had windows of a magnitude and form similar to those in churches.

Ragland, Thornbury.

During the reigns of Henry the Seventh and Eighth, houses presenting somewhat of a military appearance, but adapted chiefly for private dwellings, were constructed: Of this kind were Ragland in Monmouthshire, and Thornbury in Gloucestershire. And there were others of a still less military appearance, as Richmond and Nonsuch, Hampton Court and Whitehall.

Windsor, Warwick, Arundel, Alnwick.

Some idea of the magnificence of those castles may be formed, by examining Windsor, Warwick, Arundel, and Alnwick. And the effect will be nearer the truth, by recollecting, that, in those times, the immediate retainers were very numerous; and that each great castle was the resort of many dependent lords. Magnificence and profusion were their chief characteristics. The revenues of large possessions were wholly consumed in feeding, feasting, and lodging the dependents of the great barons. But when the contentions of the great were extinguished, the habits and manners changed, and dwellings were adapted wholly to domestic purposes.

Revival of Roman style.

Holbein.

John of Padua.

Plate CLXXVIII.

Previous to this time, the Roman manner had been revived in Italy; and by Palladio, and others in that country, applied with success to private dwellings. The first rudiments of it were introduced into England by Holbein, but he was confined chiefly to portals and porticos; as in that which was once in Westminster opposite to Whitehall, also at St James's and Wilton House. After him followed John of Padua, who built the palace of the Protector Somerset in a mixed style. He also furnished the plan of Long Leate (see Plate CLXXVIII.) in Wiltshire, for Sir John Thynne, secretary to the protector. At Long Leate, the elevation is composed of the Doric, Ionic, and Corinthian orders, crowned with a ballustrade.

Holland House.

John Thorpe.

Holland House, and that of the Marquis of Salisbury at Hatfield, are perfect specimens of the style which prevailed during the time of Elizabeth and James I. The characteristics are, very large apartments, galleries of great length, cornices and ceilings heavy and formed into deep compartments, halls frequently occupying the whole height of the house, very large square windows divided by stone mullions, and parapets composed of pediments of various and singular forms. John Thorpe was the most eminent architect of this age: Burleigh House is his design.

Sir H. Wotton.

Inigo Jones.

About this time the attention of the public was attracted by a treatise written by Sir H. Wotton, upon the excellence of the Roman style as revived by Palladio; and Inigo Jones succeeded in introducing it into private as well as public edifices. From his genius and taste we have not only derived the Roman style, but, what is of more real importance, the convenience and comfort which distinguishes English dwellings. The Queen's House in Greenwich Park, Lindsay House in Lincoln's-Inn-Fields, the east and south sides of Castle Ashbey, Lord Radnor's House at Coleshill, Berks, Stoke Park in Northamptonshire, and the Grange in Hants, are known to be from his designs.

Sir C. Wren.

Although Sir C. Wren was chiefly employed in public works, yet Hampton Court, Winchester Palace, and that designed for St James's Park, prove, that his classical taste and scientific skill were equally eminent in every department of his art.

Sir John Vanburgh.

Plate CLXXIX.

The next architect of eminence was Sir John Vanburgh, whose chief works are, Blenheim, (see Plate CLXXIX.) Castle Howard, Grimsthorpe, Seaton Delaval, and King's Weston. In all these splendid edifices there is much genius displayed, and in all of them the architect of Blenheim is distinctly to be traced. He was too much a mannerist. In the smaller buildings his defects are more conspicuous; and his heavy arches, clumsy arch stones, and glaring semicircles, are in many instances unpardonable and disgusting; but from this heavy charge there are some exceptions, as in the fine garden front of Castle Howard.

Interior of houses noticed.

The interior of the houses at this time were too much sacrificed to great halls, staircases, and galleries. These commonly occupied about one-third part of the principal edifice, and rendered the other two divisions cold and uncomfortable.

Earl of Burlington.

The Earl of Burlington, at his houses in Piccadilly and at Chiswick, produced beautiful specimens of Palladian architecture. Holkam and Houghton, in Norfolk, are magificent edifices, but partake, perhaps, too much of the French style. Wanstead, in Essex, by Colin Campbell, has more architectural merit. Stowe, in Buckinghamshire, is a splendid monument of the taste of Viscount Cobham and Lord Camelford; and Wentworth, in Yorkshire, reflects equal credit upon William, Earl of Strafford. These, and many other habitations, show the perfection to which domestic architecture was carried in England. The estimation in which it was then held, is evident from considering, that not only men of the first talents and taste, but noblemen of the first rank in the kingdom, both encouraged and practised it.

Colin Campbell.

Hitherto the restored Roman architecture had been formed entirely upon that furnished by the modern Italian architects, and was frequently employed without just discrimination as to the different characters of the buildings. This led to the introduction into apartments of delicacy, decorations which the ancients had only used in those of great dignity and magnitude. But about this time, some very ingenious artists of this country, not satisfied with this translation of taste, were prompted to examine the ruins of those ancient edifices where architecture might be found in the greatest purity and splendour. With this view, Messrs Wood and Dawkins visited Balbec and Palmyra; Stuart and Revet, Greece and the coast of Ionia; and Robert Adam, the Emperor Dioclesian's palace at Spalatro in Dalmatia. In order effectually to accomplish the objects of their missions, they not only ascertained the outlines of the several buildings, which they examined by actual measurement, but they determined the precise dimensions of each particular member and decoration. They each of them published, in a splendid style, the result of their labours, which furnished the rudiments of a new school, drawn immediately from the most refined works of the ancients.

Dawkins and Wood.

Stuart.

R. Adam.

Works by Adam.

Plate CLXXX.

Mr Adam, on his return to England, was for many years very extensively employed, and thereby had many opportunities of adorning his country with edifices constructed upon the principles of this newly acquired manner. Keddlestone in Derbyshire, Luton Park in Bedfordshire, (see Plate CLXXX.) Kenwood in Middlesex, and Shelburne House in London, reflect much credit on his genius and taste. In these works, the refined style of the ancients is introduced with great propriety, and the decorations are applied with a delicacy which was before unknown. But the Palace of Dioclesian, which formed the principal object of his study, was decorated to profusion, and was, upon the whole, an instance of the bad style into which the Romans had degenerated. His manner accordingly partakes too much of this original: His decorations, though exquisitely fine, are frequently too profuse; and many particular features accord ill with the outlines of correct Greek architecture. The street architecture of the Adelphi, and the gateway to Sion House, are instances of these defects.

The defects in Mr Adam's style were corrected by that brought from Greece by Athenian Stuart: It was now, for the first time, that architecture, as practised by the Greeks, appeared in original purity. The beautiful simplicity of the outlines, the correct propriety of the particular members, and the strict delicacy of every ornamental decoration, display the superior taste of that singular people. Besides his classical performance in the restoration of Greenwich Hospital, Mr Stuart designed the house of Mr Anson in St James's Square, and of Mrs Montague in Portman Square.

During this time, Sir William Chambers was very extensively employed as an architect. He was correct in the best Roman manner, and appears to have been constantly labouring to obtain a stiff magnificence. The Villa of Lord Besborough, and Lord Abercorn's house at Duddingston, near Edinburgh, are some of his best works.

Carr of York.

In the north of England, the late Mr Carr of York practised architecture very extensively, and in many works of considerable magnitude. Harewood House is inferior to few of the dwellings of the nobility, and is a respectable specimen of his professional skill. He holds a middle place between the stiffness of the preceding style and the variety which has lately succeeded. He is rather a mannerist, with a repetition of the extended fronts.

James Wyatt.

Plate CLXXX.

To the credit of the national taste, the Greek style has lately obtained a decided ascendency in every part of the kingdom, and the present artists have, in many instances, cultivated it with success. It is also fortunate, that Mr Wyatt, who has long been at the head of his profession as an architect, possesses sufficient taste and skill to distinguish the true beauties of his art under whatever school it is to be practised. He appears to be equally aware of the excellence of the Greek, Roman, or Gothic manners, and likewise equally successful in applying them in public edifices and private dwellings. We are sorry that our prescribed limits will not permit us to give more than two specimens of his works, (see Plate CLXXX.) but they are mostly well known, and easy of access to English artists.

General remarks.

The great influx and general diffusion of wealth, has of late introduced an improved domestic architecture in Britain. The merchants and manufacturers have, by their superior industry and ingenuity, acquired, most honourably, the means of procuring accommodation equal to that of our nobility. This demand has increased the number and dexterity of our architects, many of whom exercise their profession with much credit and skill; but our views being confined to merely carrying on a connected account of the progressive changes of the art, we must deny ourselves the pleasure of bestowing encomiums upon many deserving artists, and conclude this part of our subject with a few general reflections.

For more than a century past, whatever peculiarity

Mode of arrangement improved.

Thoroughfare apartments avoided.

Bells and water closets adopted.

prevailed in the style of external or internal decorations, the mode of arranging the apartments has been gradually improving. They have been more judiciously adapted to the nature of the climate and the circumstances of the possessor; convenience and comfort have been made the chief objects; and these have, we are convinced, been obtained to a degree of perfection unequalled in any other country. The contracting the dimensions of unnecessarily large halls and staircases, avoiding long passages, preventing the necessity of having rooms thoroughfares, the introduction of bells and water closets, and the more perfect supply and distribution of water, may be reckoned amongst the chief of these improvements.

Rejecting wings a defect.

One variation, which has lately taken place, seems rather to have interfered with domestic conveniency, and has even considerably injured external appearance,—we refer to the rejection of inferior buildings as wings. The elevation now consisting of one mass of principal building, if the local situation does not admit of having concealed offices attached immediately behind, they must either be placed in the sunk part of the main building, or at a distance from it—both of which modes are very objectionable in a country residence. On the other hand, the proper distribution of inferior buildings, as wings, afford many domestic conveniences, and also enable the architect to vary, more successfully, the outlines of his front. But this part of the subject will be treated of more at length under the Practice of Architecture.

In England, principal mansions are built upon estates.

The foregoing brief survey and observations will serve to give a general idea of the progress of domestic architecture in this country. In other countries, the climates and habits of life have created a difference in style; but as on the continent the palaces of the nobility are chiefly confined to the cities, the country residences have not been an equally important object of attention, as in England, where the chief family residences have ever been upon the estates. We have already stated, that the villas of the ancient Romans were of great extent; and if the delineations in Newton's Vitruvius are correct representations, their magnificence and elegance accorded with their magnitude; but these were the abodes of the princes of the earth, who required for their cellars a space which exceeded that which was occupied by the farm of Cincinnatus. The palaces erected for modern Italians, by Palladio, and the other restorers of the Roman manner, were also extensive and splendid; but these were also to lodge princely prelates in the zenith of the Romish church, or the princely merchants of the Italian seas. They were not the usual domestic architecture of the respective states; and were, besides, of a character ill suited to the British climate and manners.

Commerce.

Commerce.

Buildings employed for commercial and manufacturing purposes, are, in Britain, numerous and extensive. They have, from long experience, and keen emulation, been rendered very perfect for their respective offices; but these offices are so various, and so intimately blended with harbours, ports, and the operations of particular manufactures, that they must, unavoidably, be treated of under these heads. All, therefore, which can, with propriety, be mentioned here, are edifices of a public and general nature; as the exchange, custom-house, and public markets.

Edifices required.

Of the great commercial cities of antiquity, as Athens, Corinth, Tyre, Carthage, and Alexandria, we have detailed accounts only of their wars, wealth, and luxuries. Historians have been captivated by the splendid operations of rich and prosperous states, but have neglected to investigate the nature of the means by which they arrived at consequence and power. They have transmitted detailed accounts of temples, palaces, sculptures, and paintings, but have left us very much in the dark respecting the precise modes in which the business and industry of those great ports were conducted, and also of the nature of the edifices which were appropriated to the purposes of their extensive commerce, and rich and varied manufactures.

Forum.

The ancient markets were known by the name of the forum, and appear also to have included what we denominate exchange and bank. Vitruvius says, that the Greek forum was square, with ambulatories in the upper story; the Roman was oblong, with porticos and shops for bankers, and with galleries in the upper floor adapted for the management of the public revenues. The Roman forum included also many other edifices of a different nature; as the basilicæ, prison, curiæ, and were enriched with colonnades and sculpture. That of Trajan was entered by four triumphal arches, and had his magnificent column in the centre of it. Round the harbour of Carthage, we are informed, that accommodations of every kind were provided for merchants and seamen, and that, being decorated with Ionic columns of marble, the whole had the appearance of magnificent galleries.

Carthage.

Exchange at Amsterdam.

London.

In modern Europe, the Low Countries and England have carried commerce to the greatest extent and perfection, and have constructed exchanges upon very extensive and commodious plans. That at Amsterdam is of an oblong form: it is a plain building, of squared free stone, founded upon 2000 timber piles; it is 250 feet in length, and 140 in breadth; 26 marble columns support its galleries, to which there is access by a spacious staircase. The Royal Exchange of London was first built solely at the expence of Sir Thomas Gresham, in 1567. It was originally named the Bourse, but altered to that of the Royal Exchange by Queen Elizabeth, when she paid a visit to the founder in 1570. Three years after the great fire, it was rebuilt under the auspices of Charles II. at an expence of L. 80,000. The quadrangle occupies a space of 203 by 171 feet. The entrances are at the north and south sides, by two arched gateways. A very commodious arcade, or portico, occupies each side of the quadrangle. The middle space, of 144 feet by 117, is open, and has a statue of Charles II. in the centre. Over the arcades are semicircular groined arches, which spring from the caps of slender columns. In the story over them there are Ionic pilastres and windows, alternated by niches and statues. The whole style resembles the earliest practised by Inigo Jones, in the quadrangle of St John's College, Oxford. The south front is in an equally incorrect style, having very slender piers under heavy arcades supporting the whole superstructure, and two clumsy circular pediments over two Corinthian columns on each side of the entrance gateway. The same bad taste is extended to the tower, consisting of numerous, crowded, trifling parts. The lower parts of the building joining the arcades, are occupied by common shops; but the upper story affords excellent and extensive accommodations for transacting business.

Bank of England.

The Bank buildings, which are near the Exchange, are extensive, and executed in a rich style, but reflect no great credit on our national taste. The south front is composed of highly ornamented and very trifling parts. The north front differs little from a dead wall, with columns and pillars placed where it is difficult to assign them any use.

Liverpool exchange. The Liverpool exchange is, with regard to dimensions and architecture, superior to any other in England. The building originally intended for that purpose, was begun in 1749 from a design of Mr Wood, the ingenious Bath architect. It is a large square building, with a rustic basement, and upon that a magnificent Corinthian order, which is continued around the whole edifice. A range of tablets, enriched with emblems of commerce, occupy the space between the Corinthian capitals; and the pediment, on the centre part of the south front, is also filled with emblematical sculpture in high relief. The general proportions of the whole structure are good, and the execution of the sculpture is masterly. In 1796 the interior was destroyed by fire, but repaired for the town courts and offices, and an elegant cupola and dome constructed, which added to the general effect. The height from the pavement to the centre of the dome is 120 feet. It is remarkable, that this splendid building should never have been used as an exchange, the merchants preferring to meet in the adjacent street. This led to the project of converting an extensive space on the north side of this edifice into a quadrangle of commercial buildings, with arcades. The north façade extends 177 feet 8 inches, and is from the pavement to the top of the attic 62 feet 4 inches high; those on the east and west sides of the quadrangle are each 131 feet in length, and 55 feet 8 inches high. The style of the whole is judiciously made to correspond with that of the old exchange. The façade on the north side has, like it, a break or projection in the middle, upon the rustic basement of which rises a noble portico, consisting of 8 coupled Corinthian columns 25 feet high, each of the columns formed of one stone. On the entablature are placed four emblematical figures. Under this portico there is a vestibule or entrance, divided into three avenues by 32 Doric columns 12¼ feet high, with their proper entablatures, and surmounted by elegant groined arches. The arcades round the three sides are 15 feet wide. The exchange news-room in the east wing is 94 feet 3 inches in length, 51 feet 9 inches in breadth, and in the middle 31 feet 4 inches high. The ceiling is supported by 16 Ionic columns, and over this is a room of similar dimensions, appropriated for underwriters, &c. This quadrangle will be a lasting monument of the spirit and exertions of this enterprizing town, and an excellent specimen of the taste and talents of John Foster, Esq. architect to the corporation, from whose designs and directions it was erected. It was begun in June 1803, and the masonry was completed in about three years.

Bristol exchange. Bristol exchange consists of a small open square piazza, encompassed by an elegant colonnade, which supports a flat ceiling, thrown into compartments by beams, which reach from the columns to the walls; and these having enriched soffits under this part of the edifice sufficiently ornamented, the whole piazza is surrounded by apartments where business is transacted. The street front is in a style somewhat similar to the Liverpool exchange.

OF ARCHITECTURE IN SCOTLAND.

Scotland. The state of architecture in North Britain having been inferior to that in the more extensive and wealthy districts of the southern parts of the island, we have, as much as possible, avoided mixing it with the account of the progress of architecture in England; but the *Edinburgh Encyclopædia* would be accused of an unpardonable remissness, if this part of the subject was left wholly unnoticed: to avoid this imputation, we therefore insert the following sketch.

General observations. While the country was inhabited by small, rude, and nearly independent tribes and clans, and was, at the same time, exposed to incursions of the equally rude tribes from the northern parts of the continent, it is natural to expect, that the chief attention would be bestowed upon places of security, to which they could retire with their families. We accordingly find in Scotland the vestiges of two sorts of buildings apparently of the aforesaid description, whose era and mode of construction has never hitherto been satisfactorily made out by either historians or antiquarians. We here allude to the large circular towers built of rubble stones, laid in a regular manner without mortar, and to those singular structures known by the name of vitrified forts.

Vitrified forts. The vitrified forts are generally situated on high and partly insulated hills, where the space on the summit is occupied by the fortress. They consist of walls or mounds, composed of stones of various kinds and sizes, of irregular forms, without any mortar, but cemented by means of calcined pudding-stone. The interior space inclosed, varies in the several forts from 140 yards in length and 40 in breadth, to 25 yards by 15. In some, there is only one inclosing wall or mound; in others, as Craig Phadrick, there are two, leaving a space of 10 or 12 feet between them. The thickness of the vitrified walls or mounds varies from 7 or 8 feet to 40. **Probable purposes.** These structures being situated to command a great extent of country, and so that there are two within sight of each other, they appear, as well as places of protection, to have been a chain of signals. Craig Phadrick, situated a mile west of Inverness, at the north-eastern extremity of the great Glen of Scotland, upon the point of a ridge projecting considerably before the other parts of the hilly country, and facing the middle of the great bay of the Murray Firth, could readily receive notice of the landing of an enemy upon any point of its extensive shores. This intelligence could be instantly conveyed to Dun Sgrebin on the north side of Loch Ness, and from thence to Dun Jardel on the south side, and from it to Dun Deam near Fort Augustus, and thence to a vitrified fort in Glen Avis near Fort William, and from the latter place down the shores of the Linnhe Loch to the Western Isles, the southern parts of Argyllshire, and the Firth of the Clyde. If an enemy appeared on the western coasts, a similar operation could convey intelligence to Craig Phadrick, from whence it could be forwarded northward to the extensive vitrified fortress of Knock Farril in Ross-shire, and that of the hill of Cruich in Sutherland; and, at the same time, by means of Don Evan and Castle Finlay in Nairnshire, the alarm would be passed along the coast of Murray, and from thence across the valleys of the Don and Dee to the vitrified fort of Finaven in Strathmore, and thus meet the intelligence from the west in the southern parts of Scotland. It is most probable that these signals were made by means of lighting fires of wood, with which there is abundant evidence, that every hill was anciently clothed; and these intense fires, repeatedly placed against these inclosures composed of fusible materials, are considered by Sir Geo. Mackenzie, Bart. (see the article VITRIFIED FORT, which Sir George Mackenzie has had the goodness to draw up for this work,) as quite sufficient to have produced all the vitrification, respecting which, various other theories have of late years been offered. Mr John Williams, a mineral engineer, who, by publishing a Treatise expressly on the subject in 1777, first brought these structures into public notice, is of opinion, that they were constructed by raising two parallel dykes of earth or sod in the direction of the intended wall, with a space between them sufficient for its thickness, where the fuel was put in and set on fire, and upon this the fusible pudding-stone (usually found near

Various opinions.

the spot) being laid, was kept from running off by the aforesaid sod or earthen dykes; and this operation being repeated, the wall was raised to the desired height. Mr A. Fraser Tytler, professor of Civil History in Edinburgh, afterwards Lord Woodhouselee, examined these forts in 1782, and furnished an excellent paper on the subject, which is inserted in the Transactions of the Royal Society of Edinburgh. His opinion is, that the walls or mounds have been built between two rows of wooden stakes, secured together by boughs of trees, having the spaces between these rows filled with stones, earth, and trunks and boughs of trees, and that the vitrification took place during the destruction of the mass by fire. Cordiner considers each fort to be an extinguished volcano, and that the wells found in the inclosures are the craters; but in Craig Phadrick there is no well, and the space upon which the fort is constructed is a mass of undisturbed pudding-stone rock, and it would have been a singular circumstance, to have found small volcanos so conveniently situated for a chain of signals. But setting aside the theories respecting the mode of construction, it is quite certain that vestiges of these rude fortresses now exist, and that they must have been formed by artificial means, to serve the purposes of the inhabitants in a very remote period. In that view, they must be allowed to be works of great magnitude and labour, and they now form a singular feature in the country, and a subject worthy the notice of the antiquary and historian.

Circular towers, or duns.

The circular towers, which are numerous, appear to have been sometimes placed singly, as that of Dunaliskaig, on the Dornoch Firth in Ross-shire; sometimes one large tower is found, encompassed by two or three smaller ones placed about 5 or 6 paces from the large one, and from each other, as Dun Dornadilla, near Tongue in Sutherland; and sometimes several large towers are found situated at a considerable distance from each other in the same district, as in Glen Elg in Inverness-shire.

Glen Elg.

Description.

With regard to the latter, we have been enabled to give the following account of their present state, by the kindness of Mr John Mitchell, the general inspector of the parliamentary roads now carrying on in the north of Scotland, who has been so obliging as to examine and measure them at our request. Glen Elg is the name of a considerable district in the Mainland, lying opposite the south-eastern parts of the isle of Skye, from which it is only divided by a narrow arm of the sea. It consists chiefly of two valleys or glens, that is to say, Glen More or the great glen, and Glen Beg or the little glen. Both of these face towards the isle of Skye. Four of the round towers stand in Glen Beg, and they are all situated on the north-east side of its river. The first stands about a mile and a half from the sea shore, upon the west shoulder of the ridge which separates the two glens: it is considerably elevated above the bottom of the valley, and commands a view of the narrow part of the strait called Kyle Rhea, and also a considerable portion of the southern end of the isle of Skye towards the island and bay of Oronsay. This tower has been totally demolished; a circle of loose stones only distinguishes its site; they are generally large, and naturally well shaped. From this a second tower is seen, at the distance of about half a mile from the former. It stands upon a piece of flat ground close by the side of the river. It is of a circular form, and the external circumference is 178 feet. Of this, 112 feet appears above the surface of the ground, only sufficient to shew the thickness of the wall to be 10 feet; but 66 feet of the north-east quarter is still 26 feet high. This part is 10 feet thick at the foundation, and 4 feet at the top. Near the western extremity of the part which is standing, but on the northern part of the general circle, there is an entrance doorway 6 feet high, and 3 feet 6 inches wide. The bottom of this doorway is a little below the present surface on the outside, but on the same level with the surface within the tower. On entering this doorway, there is an entrance to a passage nearly in the middle of the wall, which is 5 feet 9 inches high, and 2 feet 8 inches wide at the bottom, and from 12 to 20 inches at the top, which is lintelled with flat stones. There is no other opening but the aforesaid doorway in this standing part. The difference between the top and bottom thickness of the wall is all taken off the outside by a concave batter, resembling that of the Eddystone light-house, the inside surface of the wall being nearly perpendicular. Nearly in the middle of the wall, there are four heights of passages over each other. The lower one is ascended from the doorway, by a few steps and an inclined plane to the height of about five feet. The passage, as has already been observed, is about 5 feet 9 inches high, and 2 feet 8 inches wide, and is lintelled with thin flat stones. The upper passages are from 3 to 4 feet high, and 12 to 20 inches wide. Within the tower, immediately over the doorway, there are seven small openings perpendicularly over each other, and only separated from each other by thin flag stones, which also alternately form the divisions between the passages. The lowest of these openings are each about 20 inches square, the uppermost 18 inches square. Near the other extremity of the standing part, there is another range of openings exactly similar to those already mentioned; and half way between them, there are two openings of about the same size, and on a level with the uppermost of the said ranges. On a level with the top of these openings, a course of thin flag stones project from six to eight inches all along the part of the wall which now remains. The external face of the tower is composed of stones naturally well shaped, laid in a very close and regular manner. For about six feet in height, the stones are rather of a larger size than those above them, but all are equally well laid. In the interior surface of the tower they are also well laid, but not quite so perfectly as in the external surface. In the passages the surfaces are more irregular; but in no place is there any appearance of any sort of mortar, or the use of hammer, or other instrument. From this second tower there is seen, at the distance of about 600 yards, a third, standing in the bosom of the hill about 400 yards from the river, and on ground elevated about 30 feet above it. It is of a circular form; the external circumference is 165 feet. Of this, 81 feet of the eastern quarter is 21 feet in height, the wall is 12 feet thick at the bottom, and 6 at the top. The remaining 84 feet of the circumference is about 12 feet high on the lower side, but owing to the steep declivity of the ground, the top of this part rises only to the level of the surface of the ground on the upper side. There is no entrance visible on the outside of what now remains. Nearly in the middle of the wall, there are three stories of passages divided from each other by thin flags; they are each four feet in width, and from 3 to 3 feet 6 inches in height. The bottom of the lowest passage is about 7 feet above the surface of the ground. There is in the part now standing, five openings similar to those described in No. 2. They are each from 2 feet to 18 inches square; the external surface is built with a straight batter; the internal nearly perpendicular; the masonry is composed of stones rather larger than the former, not of so good a quality, but quite as regularly laid. The whole of the interior surface of this tower appears as if it had been injured by the fire. From this third tower, at about a mile and a half still further up the glen, a fourth tower is situated upon a bold point of rock, close to and about 120 feet above the river. This is of an oval shape. Its interior diameter is in one direction 53 feet, in the other 38 feet. In the southern quarter, there is from 6 to 12 feet standing above the general surface of the rock, all the rest is demolished. In some parts, the stones are lying about the foundation, in others, part of the rock has given way; and, with the stones of the building fallen down into the river, the thickness of the part now remaining is 12 feet. On the north-east side, there is a doorway 3 feet in width, and the height is from 5 to 6 feet. At one place in the southern quarter, there is a passage 2 feet wide, and 3 feet high. The external surface of the part now standing is built of well-shaped stones, regularly laid, but not of a large size. From this tower, that which we have named, No. 3. is seen, but none of the others, and it is from No. 1. only that there is a view of the sea. There is also another of these sort of towers upon the shores of Loch Duich, standing upon a rocky eminence immediately above Tuteg ferry; and it is said the remains of others may still be traced in Glen Elg, but we have not received any authentic account of them.

Dun Dornadilla.

In the largest of the towers of Dun Dornadilla, situated near the top of Loch Tongue, in Sutherland, the walls are 30 feet high; the outer circumference is about 150 feet; the diameter of the inner area is 27 feet, which leaves about 10 feet 6 inches for the thickness of the walls, including the passage; in this passage there is a stair from the first to the second story.

Dunalaskaig.

The tower of Dunalaskaig, in the Dornoch Firth, is not situated upon any promontory, but upon the side of a steep bank, opposite to the vitrified fort which occupies the top of the conical hill of Criech. It stands about 50 feet above the level of the sea, and the view from it is rather confined. The present height, on the upper side next the public road, is about 11 feet; but on account of the steepness of the bank, the foundation of the lower side is about 7 or 8 feet under the level of that on the upper side. The form appears to be exactly circular; the diameter of the inner area is 31 feet; and the thickness of the walls, including the passage between them, is about 12 feet. On the inside of the inner wall, at about five feet above the present surface of the ground, there is a ledge or offset all round, of about one foot in breadth, which of course reduces the diameter, at this place, to 29 feet; but from this the face of the wall tapers downward, so that at the surface of the ground the diameter is 31 feet. Below the level of this ledge there is only one opening; this is on the north east side, and is 4 feet 9 inches high, 3 feet 2 inches wide at the bottom, and 2 feet 9 inches at the top. On each side of this opening there is a jamb with a recess, as if to receive a door to be fastened on the inside; there are also holes, apparently for wooden bars, at the back of the door immediately within the jambs. On each hand, there is an opening like the entrance to a passage in the middle of the wall; the one is 1 foot 6 inches, and the other 2 feet wide, and 3 feet 6 inches high. Round the outer wall there is no other opening but this, but in the inner wall there are four openings placed immediately upon the aforesaid ledge, and opposite to each other; one just over the entrance doorway is 4 feet high and 3 feet wide, the others are partly broken down. In the passage between the walls there are steps of a stair; this passage is about 3 feet 3 inches in width at the entrance, but diminishes to about 18 inches near the upper part; the middle is 4 feet 6 inches in width, from the steps or lintelling over the head; the height is from 5 feet 9 inches to 6 feet. There have also been two other staircases between the walls. The masonry is composed of stones similar to those now lying in the immediate neighbourhood. They are large, naturally well-shaped, and laid with great regularity; but neither externally nor internally, is there any appearance of artificial dressing by means of a hammer or other instrument. From the light to the passages in the middle of the walls, having, in all these structures, been procured from the inside area, it would appear that this never was covered at the top; and yet, in those northern countries, it is improbable that people could remain long thus exposed in these open inclosures; it is equally improbable that the narrow staircases and passages could be employed as permanent dwellings. These buildings must therefore have been only signal towers, or very temporary places of refuge; or they may perhaps have been employed for religious purposes; but whatever were their original destination, it is sufficient, in the present enquiry, to know that they were all built in a regular manner without mortar.

Roman works.

Lime mortar.

During the 400 years in which the Romans possessed Britain, the modes of building were completely changed: the introduction of lime mortar was alone sufficient to form a new æra. The fortified ramparts constructed between the Forth and Clyde, and Newcastle and the Solway Firth, were a school with which the northern mountaineers, from their constant efforts to destroy them, were, no doubt, quite familiar. The art of combining into one compact and comparatively impenetrable body, the smallest and most irregular stones, must have immediately struck a people eager to seize any means of obtaining more perfect protection. We accordingly find the vestiges of very old towers constructed in this manner upon insulated rocky promontories, along the whole of the sea coast of Scotland; also on the shores and islands of the numerous inland lochs; and in the passes and commanding stations of the mountains. They are most usually single towers of three stories in height, but not unfrequently, in those reckoned royal residences, the buildings were of greater extent, as Inverlochy castle in Lochaber, which is a regular square, with round towers at the angles: or they consisted of one plain square only, as Balvarie, Elgin, and Duffus, in Moray. In other places, in order to occupy the whole rocky or insulated site, they were of an irregular shape, as at Urquhart upon Lochness, and Dunstaffnage upon Loch Etive; and Ruthven in Badenoch stood upon a neck of high ground projecting into a marshy plain, terminating in a conical mound, on which the castle was built; the area on the top was 100 yards by 30, the south wall 9 feet in thickness, the other side was four feet; there were two turrets at the northernmost angles. This was the seat of Comyn, Lord of Badenoch.

Old castles of various forms.

What relates to the protection of towns, forms a part of military architecture; and in the country, until a very late period, the rude and turbulent chieftains continued to inhabit their castellated towers.

Ecclesiastical edifices

With regard to places of worship, unless the circles of rude stones placed in the ground are considered to have been appropriated to religious purposes, nothing can be traced north of the Tweed prior to the 7th century. About this time Old Melrose, Coldingham, and a church at Tynningham were founded. (See Chalmers's *Caled.* vol. i.) Respecting the first of these, it is said, that within 16 years after Lindisfairn in Northumberland, (viz. 635,) a religious house was established in a peninsula on the south bank of the Tweed at Maol-ross. On the death of Aidan, the celebrated Cuthbert entered the monastery of Melrose as a monk under Roisel. Coldingham was founded during the reign of Edgar, who considered himself much indebted to St Cuthbert for his crown; and it is also said, that in 1098, the priory of Coldingham was founded by the abbot of Durham, who sent monks hither. Notwithstanding this introduction, ecclesiastical architecture made little progress in Scotland till the time of David I.; but during his reign it was carried to an extent apparently beyond the resources of the country. The following edifices are known to have been founded by that prince:

Edifices founded in the time of David I.

The cathedral of Glasgow	in the year	1129
Ditto . . . . . . Dunkeld	. . ditto . .	1130
Ditto . . . . . . St Andrew's	ditto . .	1140
Ditto . . . . . . Aberdeen	. . ditto . .	1154
The abbey of Holyrood-house	ditto . .	1128
Ditto . . . . Kelso	. . . . . ditto . .	1128
Ditto . . . . Melrose	. . . . ditto . .	1136
Ditto . . . . Kinloss	. . . . . ditto . .	1141
Ditto . . . . Jedburgh	. . . ditto . .	1147
Ditto . . . . Dryburgh	. . . ditto . .	1150
Priory of Urquhart in Moray	ditto . .	1125

The chartulary of Elgin not going beyond 1200, we are ignorant when it was erected into a bishopric, but it has most probably been also indebted to David I. In 1178, William the Lyon founded the great abbey of Aberbrothick; and in 1230, Alexander II. the priory of Pluscardine in Moray.

In the best style.

These structures, although inferior in magnitude to many in England, were yet of no inconsiderable size, and they were generally in the best style of Gothic architecture. As each of them will be more particularly described when treating of the places where they were situated, and will also be referred to under the Practice of Architecture, the following dimensions may, for the present, enable the reader to form a tolerably correct idea of their magnitude.

St Andrew's. Glasgow. Elgin.

The cathedral of St Andrew's was 370 feet in length, 62 feet in breadth, and the length of the transept was 322 feet. The cathedral of Glasgow is 339 feet in length within the walls, 72 in breadth, 90 in height from the floor of the choir to the roof, and the tower and spire are in height 228 feet. The cathedral of Elgin is 284 feet in length, 71 in breadth, the transept is 114, and the central tower 198 feet. The abbey of Aberbrothick is 370 feet in length, 62 in breadth, and the transept 165 feet. Under the head of Practice will be found a very minute description of each apartment of the priory of Pluscardine.

Collegiate churches.

Chalmers says, that the collegiate churches were not known in Scotland till the reign of David II. The first was established at Dunbar by Patrick, Earl of March, in 1342; the next was at Dunglass in 1403 by Sir Alexander Home of Home. After this several others were established in Haddingtonshire. In 1446, William St Clair, Earl of Orkney and Lord of Roslin, founded a collegiate church at Roslin, for a provost, six prebendaries, and two choristers, and endowed it with various lands and revenues. It was consecrated to St Matthew the apostle. The chapel is justly admired as a singularly beautiful piece of Gothic architecture; the inside is 69 feet long, and 34 in breadth; the roof is supported by two rows of clustered columns, eight feet high; the middle aisle is one continued arch, enriched by exquisite sculpture. The comparative smallness of the dimensions of this edifice, gives it the appearance of a fine model of a Gothic cathedral.

From this general sketch we shall proceed to a brief detail of the progress of architecture in the two principal cities in Scotland; and we conceive it will be most distinct and satisfactory to state the progress made in each city separately, beginning with the capital.

Architecture in Edinburgh.

This city appears to have taken its name from Edwin, a Saxon prince of Northumberland, who began his reign in 617. For several centuries afterwards, the castle only seems to have been of any importance. It is uncertain at what period it came into the possession of the Scots: It is known that Margaret, the widow of Malcolm Canmore, died in it on the 10th November, 1093. The first distinct information respecting the city, is derived from the charter granted by David I. in 1128, in favour of certain canons regular, for which he founded the abbey of Holyrood-house. From this instrument it appears, that Edinburgh had previously been erected into a royal burgh. In the reign of Alexander II. the first parliament was held in Edinburgh in 1215. In 1255, the daughter of Henry III. of England, the betrothed queen of Alexander III. had the castle appointed for her residence. Robert I. bestowed upon the burgesses of Edinburgh the harbour and mills of Leith. In 1437, the kings of Scotland had their usual residences in Edinburgh; and parliaments were frequently held in it. (See Arnot's *Hist. of Edinburgh.*) By this time the city must have been extensive and well built, for a writer of the 16th century, (Braun Agrippinensus, lib. 3. *voce* Edin.) says, "In this city there are two spacious streets, of which the principal one, leading from the the castle, is paved with square stones. The city itself is not built of bricks, but of square freestones, and so stately in their appearance, that single houses may be compared to palaces. From the abbey to the castle there is one continued street, which, on both sides, contains a range of excellent houses, and the better sort are all built of hewn stone." Few cities in the island could, at this time, justify a similar eulogium.

Holyrood House. Abbey. Fine Gothic. Roslin.

Although we have accounts of many religious houses in Edinburgh which have fallen into decay, yet, as far as regards the architecture, excepting the abbey of Holyrood-house, there is no vestige deserving of much notice. This, as has already been observed, was founded by David I. in 1128, and endowed with extensive privileges and jurisdiction. It suffered much when the English burnt the palace in 1544, but was speedily repaired. At the Restoration, King Charles gave it a complete repair, and ordered that it should be set apart as a chapel royal; a throne was erected for the sovereign, and twelve stalls for Knights of the Thistle; but its splendour was of short duration, for, in consequence of a mass having been celebrated in it, in the time of James VII. the populace sacked the inside. In 1758, the roof was injudiciously covered with heavy stone slate, in consequence of which it fell down in 1768; since that time, no attempts have been made to repair it. This edifice is of the finest style of Gothic architecture; part of the arches are highly pointed; on the south side are flying buttresses; on the other side they are solid, but of an elegant form, and ornamented with canopied niches and pinnacles on the top; the windows of this side are but slightly pointed. This variation of style arose, no doubt, from its having been repaired at sundry times. Dallaway, in his *Anecdotes of the Arts in England*, p. 30. says, "Of Gothic architecture in Scotland, the most beautiful pieces which remain entire, have their date in the prior part of the 15th century. They are the chapel at Roslin, and that in the palace of Holyrood-house, the last mentioned of which was finished about 1440, by King James II. of that realm. Their sides are flanked with flying buttresses,

History.

like those at King's College and Westminster, but with happier effect; because in a purer style.

Parliament House.

The Parliament House was begun in 1631, and completed about 1640, at the expence of L. 11,600. The style is similar, in many respects, to that of Heriot's Hospital; and therefore, probably a design of Inigo Jones. Its front to the square was plain, but respectable; it had hanging square turrets at the extreme angles, with a round tower at the interior angle of the square. Some of the windows had pointed pediments; others flat cornices, with sculptured ornaments over them. The principal entrance had pilasters, and a flat entablature. There were statues over the pilasters, and a tablet, with a pediment over it, in the middle between the pilasters. The parapet, along the front, was a sort of fret work. The great hall is 122 by 49 feet, with a statue of Lord President Forbes, by Roubilliac. This edifice is now considerably changed, to receive the new courts of justice.

Heriot's Hospital.

Heriot's Hospital is known to be a design of Inigo Jones. It was begun in July 1628; it was interrupted by the national disturbances in 1639; was again proceeded with in 1642, and completed in 1650, at an expence of about L. 30,000. It consists of one square court, encompassed with buildings; it has projecting turrets at the external angles, and a square tower over the entrance, which is carried up to double the height of the rest of the building, and finished with a cupola. Belts or string courses divide the several stories. The windows have pediments over them; some of these are pointed, some circular, and open in the middle. The entrance archway has coupled Doric columns with fully enriched entablature; but this is broken by heavy trusses, having grotesque Gothic ornaments. The mouldings round the arch terminates in a scroll; and there are pinnacles over the coupled columns. Immediately above the archway are twisted Corinthian columns: the whole frontispiece is crowned and surrounded by minute sculptures. The interior of the square, which is about 32 yards by 30, has arcades on two sides, and towers at the four angles, in which are stairs. The windows of three sides have pilasters and regular sculptured ornaments over them. In the upper row, on the north or entrance side, in the middle of the sculpture over the windows, there are small niches, with busts in them;—this produces a fine effect. On the south side is the chapel, with very large Gothic windows; but the entrance door has small coupled Corinthian columns, with a circular pediment over each pair, and both these surmounted by a strange sort of circular open pediment.

Change of styles.

We know of no other instance, in the works of a man of acknowledged talents, where the operation of changing styles is so evident. In the chapel windows, although the general outlines are fine Gothic, the mouldings are Roman. In the entrance archways, although the principal members are Roman, the pinnacles, trusses, and minute sculptures partake of the Gothic. The outlines of the whole design have evidently been modelled on the latter style, of the baronial castellated dwelling. It forms one of the most magnificent features of this singular city, and is a splendid monument of the munificence of one of its citizens, George Heriot, a goldsmith in the reign of James the VI.

Holyroodhouse.

We have no direct evidence at what period the palace of Holyroodhouse was first built. The north-west towers were erected by James V. The palace was burnt by the English, in the minority of Queen Mary, but speedily repaired. It then consisted of five separate courts. Some small alterations were, it is said, made by Inigo Jones, at the time he returned from Denmark with the queen of James I. Great part of this palace was burnt by Cromwell's soldiers. The present edifice was designed by Sir William Bruce, a celebrated architect in the time of Charles II. and executed by Alexander Mylne, a mason, to whom a monument has been erected near the Old Abbey. It consists of one square, three sides of which have three stories, composed of the Doric, Ionic, and Corinthian orders. Round the interior of the square, there is an arcade. The west side, in which is the entrance, is only two stories high. Its external façade is a mixed architecture, having a round castellated tower at each extremity. The entrance is ornamented by a fully enriched Roman Doric, with a whimsical shaped open pediment, over the centre of which there is a cupola, with very small Corinthian columns, having its covering or roof in the shape of an imperial crown. Had the whole of the entrance front correspouded with the towers at the extremities, it would have been expressive of strength and protection; as it is, we can hardly wish them exchanged for features of Roman architecture. The external front eastward has a distinct order to each of its three stories; the entablature being continued along the whole front without a break, has a fine effect; the roof is after the French fashion, very high and concave. Though the inside of the square, by the introduction of three orders, has the parts rendered minutely small, yet the outlines being free of unnecessary projections and recesses, and the two upper rows of windows being large and plain, the whole exhibits a correctness and simplicity not frequently met with.

History.

Entrance described.

East front.

Inside of the square.

Royal Exchange.

The Royal Exchange, situated on the north side of the High Street, was begun the 19th of June 1754, and cost L. 31,457. It is in the form of a square. The north side is 111 feet in length; in the centre of this side, there are four Corinthian pillars. The south, or side next the street, is composed of an arcade, and is only one story high.

College.

Of a more recent date, the College, which formerly consisted of mean buildings, was begun to be entirely rebuilt from a design by Robert Adam. It is yet far from being completed; but the street front, and the southwestern part of the square, have been roofed. We do not consider the site of the edifice as favourable. The noisy streets by which it is surrounded must be equally obnoxious to the professors and students. The justly celebrated architect has added nothing to his fame by the street front. The projections in the centre and at the extremities destroy simplicity. The large semicircular openings near the base of the extreme breaks, appear to weaken those parts which ought to appear strongest. The large semicircle over the entrance is objectionable, being too glaring a feature. The portico is too small for the front, and it is also unnecessarily broken by projections and recesses. In the interior of the square, the rich Ionic arcade in the angle accords but ill with the meanness of the other part which has been executed.

Courts of justice.

In the new Courts of Justice now building in the Parliament Square, the Ionic screens of columns are raised upon too high a basement; and a number of breaks destroy the unity of the design. Indeed, we much doubt if any arrangement of Greek or Roman architecture could, in this situation, produce an effect equally fine with that of the style which has been superseded.

General remarks.

The buildings we have hitherto noticed are all situated in the old part of the city of Edinburgh; and, beside these, there are several others of no inconsiderable merit, but our limits preclude all attempts at describing them. For farther information we must therefore refer to Mr Arnot's excellent book. But, previous to quitting the ancient part of the city, we cannot help expressing our regret, that any style of architecture later than the castellated dwelling has been admitted within its precincts. The smooth regularity of outline, projecting or open colonnades, corridors, and spacious Venetian windows, invented in a more southern climate, are little in character with the irregular but magnificent features of an ancient British city. We are aware, that, in regard to the appropriation of private property, all direct interference is inadmissible; but, in public buildings, the proper character might have been preserved, and, by the aid of judicious architects, the style of even private buildings might have been preserved sufficiently correct. The local boundary of the ancient city is, however, perfectly distinct, and in one evidently wholly new there is less impropriety in a change of style. Even here we doubt if the Greek or Roman modes be the most appropriate; but these having been generally adopted, we shall, in the present hasty remarks, consider them as subject to those regulations and practices.

New Town.

Register Office.

In the New Town, the first building in point of time or consideration is the Register Office, which contains the public records of the kingdom. It is situated fronting the bridge which connects the new with the old city. It would have appeared to greater advantage if removed farther back, upon the more elevated ground which is immediately behind it. Mr Robert Adam made the design, and it was begun on the 27th June 1774. This building, both externally and internally, reflects great credit on the architect. The original design, as given in the works of Robert and James Adam, has in the centre a magnificent circular saloon, covered and lighted by a dome. This saloon is surrounded by small apartments, and the whole of these inclosed by buildings in the shape of a parallelogram. By this ingenious contrivance, the admission to all the apartments, and affording light to the whole, is perfectly accomplished. Only a part of this masterly plan has been executed, but even this composes an apparently complete building. That the external features have also been the result of much attention, is evident from the chasteness of the details. A greater degree of magnificence, we will venture to say, might have been obtained by keeping the basement of the principal front lower, adding to the magnitude of the order, and continuing a full colonnade for the whole distance between the breaks at the extremities of the building; also continuing a range of pilasters, with full entablature, along each end; having no Venetian windows, nor semicircular arches, in the principal front; making fewer windows, and those nearly double their present size, in the upper range; having no pediment in the centre, nor small cupolas at the extremities; and by rendering most part of the roof visible. The terrace in the front has a good effect; but one direct broad flight of steps up to it, would have been preferable to the present small circular ones.

St Andrew's Church.

The public building next in importance is St Andrew's Church, situated in the north side of George's Street. The body of this church being elliptical, does not harmonise with the square portico with which it is united. The double row of small windows, in the body of the church, we hold to be quite incompatible with the true character of a sacred edifice; and its being without either pilasters, or even a full entablature, increases the meanness of its appearance. The steeple being composed of Roman architecture and a Gothic spire, is much inferior to the simply plain but finely tapering English spire, rising from a lofty, plain, square tower. It is, however, superior to most of the sort in Scotland, and is ornamental to the town. Indeed, any fabric, even of inferior merit, which rises above, and interrupts the uniformity of straight roofs, is here advantageous.

Physicians Hall.

On the south side of George's Street, nearly opposite the last-mentioned edifice, stands the Physicians Hall: the principal features of which compose the most chaste design of any public building in the New Town. The basement is kept sufficiently low. There is a noble straight flight of steps in the front. The portico has a bold projection; and the columns rise up to the entablature which forms the upper member of the building; and this entablature is continued round the ends. The pediments over the windows might have been spared; and attics have always, but more especially in a public building, a mean appearance. The general effect, as a piece of street architecture, is much injured by the rude gable ends of the houses on each side: They ought to have been made in character with it. At present, this fine building appears to have been accidentally pushed back from its proper situation. It was designed by Mr Craig, the architect who made the plan of the New Town.

St Andrew's Square.

To the east, George's Street is terminated by St Andrew's Square; and on the eastern side of this square there stands a fine house built by Sir Lawrence Dundas, from a design by Sir William Chambers. It is placed considerably back from the line of the other buildings; and a house on each side is made to have, in front, the appearance of forming wings to it; but, as they stand in a line with the other houses in that side of the square, the space which intervenes between them and the main, or centre house, being only inclosed by a low rubble wall, the apparent connection is destroyed. The large Ionic columns, upon the front of the wings, are too bold for the feeble Corinthian pilasters of the central building, and these are, besides, raised upon too high a basement. It would lessen the clumsiness of the Ionic columns if they were fluted. They stand very properly upon a plinth; and there are pilasters at the angles of the wings; but the columns are advanced before the line of the pilastres, and an attic story is placed over them.

Charlotte Square.

To the westward, George's Street is terminated by Charlotte Square. Its buildings are more uniformly designed, and more highly ornamented, than those of the other square; but we have to regret a too frequent repetition of unmeaning projections and recesses, also of semicircular and glaring Venetian windows. A church, now building on the western side, is yet too little advanced for us to judge what effect will be produced. We are glad to see provision made for a portico of considerable magnitude, placed within a moderate distance of the surface of the ground.

General Remarks.

The general plan of this new town is regular and convenient, and there is a proper subordination of streets. In this northern climate, and exposed situation, perhaps it would be an improvement if the cross streets on each side of George's Street had not been opposite to each other, and if the length and uniformity of the principal streets had, in some instances been interrupted. We are surprised, that it has never occurred to architects employed in laying out new towns, that monotony ought studiously to be avoided. The New Town of Edinburgh is greatly injured by it. Here the streets are spacious, and the houses excellent; but the uniformity is tiresome, and the repeated sameness of all the divisions resembles a panorama of square battalions. To any person of observation it must be evident, that the High Street in the Old Town has a much finer effect than any in the New Town: Also, that the high street of Oxford and Parliament Street, Westminster, are infinitely superior, in point of general effect, to the new streets about Portman Square, Portland Place, or Russel Square, London.

Glasgow.

Cathedral, 1129, A.D.

The only entire cathedral in Scotland.

The city of Glasgow is situated in one of the finest valleys of Scotland, and where the island is most contracted in its breadth. It stands on the banks of a navigable river, and on the great Roman road which passed through the province of Valentia, and has in its neighbourhood an inexhaustible supply of coal. From these circumstances it very early became a place of importance, and, it would seem, also an episcopal see; for Bingham (b. viii. p. 10.) says, that about the year 448, Bishop Ninian of Glasgow built an episcopal church on the confines of England, at Whithorn in Galloway. But from this time we know very little respecting its progress till the year 1129, when Achaius, preceptor to David I. was appointed to the see. He began to rebuild and adorn the cathedral church, and, although in a very early stage of its progress, consecrated it, in presence of the king, upon the 9th July 1136. At this time it enjoyed the tythes of the lands of Peebles, Selkirk, Roxburgh, Dumfries, and the stewartry of Annandale, bebesides lands in Cumberland. In 1174, Jocelin, abbot of Melrose, was consecrated bishop. He enlarged the cathedral, and dedicated it on the 9th July 1197. Previous to this ceremony, William the Lyon granted a charter, erecting Glasgow into a royal burgh. The completion of this cathedral was accomplished by degrees, at periods remote from each other. In 1240, William de Boddington made reparations and additions. Between 1387 and 1408, when Matthew Glendinning (of a family of that name in Eskdale) was bishop, the steeple, which was of wood, was burned down. Bishop William Lauder laid the foundation of the vestry, and built the great tower as far as the battlements, from 1408 to 1425. Between 1484 and 1508, Bishop Rob. Blackadder founded, and built to its present height, the great south aisle, and also the south cross. In 1560, Bishop Beaton, alarmed by the interference of the reformers, withdrew to France, and carried with him all the valuables of the cathedral. This is now the only entire cathedral church upon the main land of Scotland. All the windows, buttresses, roof, and spire, remain nearly perfect, and promise long to continue the chief ornament of the city.

St Andrew's Church.

Of the other churches, that of St Andrew's, in the middle of a square of that name, is the principal. Both externally and internally, it is nearly an exact copy of St Martin's in the Fields, London, and, of course, partakes of its excellencies and defects. The staring vases along the parapets, detract from simplicity; and the steeple (which differs entirely from the original) is lofty, but so ill designed, that it appears to be narrowest at the base.

Spires resemble pagodas.

There are many other churches in Glasgow, but they are all very inferior to this. They have uniformly two rows of windows; and their spires being a repetition of square boxes placed on each other, having their divisions distinctly marked by cornices, they very much resemble the eastern pagodas. Several are carried up nearly perpendicularly, others taper a little, and are (as that of St Enoch) finished with the point of a spire.

New church, St George's Square.

Church on the south bank of the Clyde.

Hutcheson's Hospital.

There has lately been a church built on the western side of George's Square, in the front of which are a multitude of small breaks. There are pilasters at the extremities, and columns on each side of the entrance door, which seem to have very little connection with each other. Over these columns rise a sort of turrets, which run up part of the steeple. The steeple is itself composed of six or seven different divisions in height. Although there are only one row of windows in the front, there are two in the sides of the church. The architect has, on the whole, deviated widely from our ideas of simplicity and propriety. In a still clumsier style, a church is now constructing on the southern bank of the Clyde. The front, consists of three stories of regular dwelling-house looking windows. The upper ones are small attics. The sides of this church do not correspond with the front; and the tower or steeple is in the pagoda style. This total departure from the character of a church is the more remarkable, as we are informed, that the same architect designed Hutcheson's hospital; and the outlines of its front, which faces Hutcheson's street, appears to us correct and fine. Here the basement is perfectly subordinate to the order, which reaches to the roof, and has its entablature passing unbroken along the front. Within the colonnade there is only one row of windows, which conveys a distinct idea of one apartment only, and there being niches near the extremities, the whole is expressive of a public building. The steeple, though unfortunately still composed of separate divisions, tapers gradually from its pedestal. Several of the minuter ornaments of this edifice might be changed or omitted with advantage.

Theatre.

Buildings by Adam.

In the front of the theatre, by the same architect, the proportion between the basement story, and the fine Ionic order above it, is also well preserved; but the unnecessary projection of the two pair of columns, the arches over the lance doors, and small circles in the attics, detract greatly from simplicity. In this city, there are several public buildings designed by Robert Adam, viz. the infirmary, trades-hall, and assembly-rooms. They are fine buildings, and ornamental to the city; but the profusion of projections, recesses, Venetian windows, and large semicircles, are destructive to chastity of design.

Hunter's Museum.

College.

Courts of Justice.

Hunter's museum, in the college garden, is a correct regular building. The portico, which is Roman Doric, rises from the pavement to the roof, but the cornice only is continued round the other parts of the building. The whole does great credit to the architect Mr Stark. The garden front of the college has been lately new modelled from a design by Mr Peter Nicholson, whose excellent elementary architectural works have, in many instances, tended to connect science with taste. In this front, he has introduced the Greek Doric columns in the central part, and panelled pilasters at the extremities. We regret he has not continued these columns to be regularly connected with the aforesaid pilasters, and thereby have excelled Mr Wyat's new front at Oriel college, in Oxford. The balusters at the windows might have been spared in Greek architecture. The new courts of justice now erecting, from designs by Mr Stark, promise some fine features. The Doric order upon a well proportioned basement, occupies the whole height of the front. There is reason to expect a bold portico; but we regret, that its connection with the extremities is not perfectly made out by pilasters, and that the architect has not contrived to have one row of large windows only in the principal front. The dressing in the Vanburgh manner over some of the windows, do not accord with a chaste Greek Doric, when the projection of the pilasters at the extremities are too delicately small.

General remarks.

The whole of Glasgow as a city, has, in point of architecture, more merit than is generally met with. Standing on comparatively level and smooth ground, it has none of the wild irregularity of old Edinburgh, yet the Tron and Argyll streets partake of the grandeur of the High-street of the capital. The style of the new streets in Glasgow, accords sufficiently with those of the more ancient parts. There being a considerable difference in the fronts of individual dwellings, and these frequently mixed with public buildings, a street architecture is found here much preferable to that of the new town of Edinburgh.

Other towns.

In the towns of Stirling, Linlithgow, and Dunfermline, may be seen the remains of royal palaces. They have been castellated squares, with chapels. That at Linlithgow is upon a magnificent scale, and has still a very striking effect. At Stirling, the palace built by James V. has its northern and western fronts in a very peculiar style, which deserves the attention of the young architect.

Hopetoun house.

Fleurs.

Gordon castle.

Pennycuik.

Duddingstone.

Melville castle.

Culzean house.

Eglinton.

Wemyss.

Roseneath.

Plate CLXXXI.

After the Roman architecture had been revived in Britain, the Scots imitated their southern neighbours in abandoning the castellated dwelling, and adopting the Palladian style. In 1698, the villa of the Earl of Hopetoun was begun upon the south bank of the estuary of the Forth, from a design of Sir William Bruce, the architect of Holyrood-house. The wings were afterwards added by Mr Adam. The beauty of the situation, and the magnificence of the structure, are well known to form a principal feature in a scene which, for extent, richness, and variety, admits of few equals. This taste in architecture was extended over the kingdom, from Fleurs, the seat of the Duke of Roxburgh near Kelso, to the superb dwelling of the Duke of Gordon on the coast of Moray. In 1761, Sir James Clerk, a man of genius and fine taste, built his elegant seat at Pennycuik, in Mid-Lothian. It is a regular square edifice; the basement and order are well proportioned; it has a bold portico of six Corinthian columns; the entablature runs round the whole building; and one row of large windows in the front corresponds with this fine order. In the same county, Duddingstone house is an equally correct design by Sir William Chambers; and Melville Castle has been rendered, by the ingenuity of Mr Adam, a still more magnificent and appropriate feature in this part of Great Britain. The same architect, with his usual fertility of invention, has in Culzean house, on a bold promontory on the coast of Ayrshire, rendered the seat of the Earl of Cassilis a just resemblance of a Roman villa as described by Pliny. Of a still more recent date, are the extensive and finely castellated structures, raised in the same county, by the munificence of the Earl of Eglintoun, and the Countess of Loudon. But perhaps the most extensive and magnificent of all the modern Scottish structures, is Gossford house, built by the Earl of Wemyss, in East Lothian, from a design by Robert Adam; though one little inferior has been erected by the Duke of Argyle at Roseneath, (see Plate CLXXXI.) from designs by the late Mr Bonomi, an ingenious Italian architect, who long practised his art with much success in England.

General remarks.

Having now, we trust, adduced a sufficient number of instances, to convey to the reader a distinct idea of the progress of architecture in Scotland, the nature of this work not admitting of more, we must, therefore, deny ourselves the pleasure of following the ingenious architects of the present day through many works, which reflect great credit upon their taste and skill. We have reason to look forward with confidence to the time, when not only the necessity of having recourse, on important occasions, to the metropolis of the empire for properly qualified artists, will be superseded, but that, emulating the well established fame of her literary characters, Edinburgh will produce a decided superiority of talent in the principles and practice of architecture.

Part II. PRINCIPLES OF ARCHITECTURE.

Not explained by the ancients.

Although, in all civilized nations, architecture has been considered an object of importance amongst men of genius, learning, and scientific skill, yet very few have afforded any satisfactory account of its principles. From Vitruvius to our own times, we have been told of grandeur, order, proportions, harmony, &c.; but it has never been distinctly stated upon what principles these are founded, nor by what means they are to be attained. This very necessary and important art has, therefore, hitherto been too frequently directed by capricious fancy; and the expence and durability of its works, have alone prevented it from experiencing changes equally rapid with those of furniture and dress.

Theories of moderns.

Professor Stewart.

Of late years, men of distinguished talents have bestowed much attention upon subjects connected with this art. To state the various theories which have been advanced, would much exceed our limits. We shall therefore only observe, that the works of Burke, Price, Knight, Reynolds, and Hogarth, afford elaborate and various information; and that the radical errors of those eminent men are fully exposed by Professor Stewart, in his Philosophical Essays upon beauty, sublimity, and taste, more especially the latter, which he proves to be chiefly an acquired faculty.

"The fact seems to be (as Mr Stewart observes) the mind when once it has felt the pleasure, has little inclination to retrace the steps by which it arrived at it. It is owing to this, that taste has been so generally ranked among our original faculties, and so little attention has hitherto been given to the processes by which it has been formed. Dr Gerard and Mr Alison, indeed, have analyzed, with great ingenuity and success, the most important elements which enter into its composition, as it exists in a well-informed and cultivated mind."

Principles correctly made out by Mr Alison.

Fortified by the opinion of this eminent philosopher, we with confidence state an opinion which we have long entertained, that it is from Mr Alison's *Essay on the Principles of Taste* alone, that a satisfactory knowledge of the principles of architecture is to be obtained. We shall therefore endeavour, in a cursory manner, to exhibit his general views of the subject; and, for more perfect information, refer the reader to his elegant and philosophical work.

In treating of the sublimity and beauty of the material world, Mr Alison observes, "It cannot be doubted that many objects of the material world are productive of the emotions of sublimity and beauty: Some of the fine arts are altogether employed about material objects; and by far the greater part of the instances of beauty and sublimity which occur in any man's experience, are found in matter, or some of its qualities; on the other hand, it must be allowed, that matter in itself is unfitted to produce any kind of emotion." And, again, "But although the qualities of matter are in themselves incapable of producing emotion or the exercise of any affec-

Effect of association.

tion; yet, it is obvious, that they produce this effect from their association with other qualities." And, "in works of art, particular forms are signs of dexterity, of convenience, of utility;" and, "in such cases, the constant connections we discover between the sign and thing signified, between the material quality and the quality productive of emotion, renders the one expressive to us of the other, and very often disposes us to attribute to the sign that effect which is produced by the thing signified."

Colours, form, and motion.

That beauty or sublimity is to be ascribed, not to the material, but associated qualities, is shewn by a great variety of illustrations; in regard to the sense of hearing, whether the sounds are simple or composed, and likewise as to the objects of sight, which are colours, form, and motion.

Of Form.

Architecture being so much affected by all that relates to form, it is necessary to attend carefully to what this enlightened philosopher has advanced respecting it. He states, "of all the material qualities, that which is most generally and naturally productive of the emotions of sublimity and beauty, is form; other qualities may be separated from most objects, without destroying their nature; but the form of every material object, in a great measure, constitutes its nature and essence, and cannot be destroyed without destroying the individual subject to which it belongs. From whatever cause, therefore, the beauty of any material object proceeds, it is natural to ascribe it to the form, or to that quality which most intimately belongs to the object, and constitutes its essence to our senses; the common opinion, therefore, undoubtedly is, that forms, in themselves, are beautiful; that there is an original and essential beauty in some particular forms, and that this quality is as immediately discernable as the forms themselves."

Qualities of which it is expressive.

Productions of art.

Having premised thus much, he proceeds to state, that the beauty and sublimity of forms arises altogether from the associations we connect with them, or the qualities of which they are expressive to us, and shews, with great accuracy, the different expressions of which forms are susceptible, and which are the foundation of that sublimity and beauty which are ascribed to them. Of inanimate forms, the principal expressions seem to be, 1st, The expressions of such qualities as arise from the nature of the bodies distinguished by such forms; and, 2dly, The expression of such qualities as arise from their being the subject or production of art. The first constitutes their natural, the second their relative, beauty; besides the expression they acquire from accidental associations, which may be termed accidental beauty.

Natural and relative beauty.

Height, depth, length, and breadth.

Conclusions.

We are next taught, that the natural sublimity of inanimate forms arises from two sources; 1st, From the nature of the objects distinguished by that form; and, 2dly, From the quantity or magnitude of the form itself. Thus forms which distinguish bodies connected with danger, power, durability, splendour or magnificence, awe or solemnity, are in general sublime; magnitude is sublime, as associated with power or strength; with height, it is expressive of elevation and magnanimity; with depth, of danger or terror; with length, of vastness, when apparently unbounded of infinity; and with breadth, it is expressive of stability. But that magnitude is only sublime in consequence of being expressive of those qualities, is shewn by many illustrations. The conclusions which follow, are, 1st, That there is no determined magnitude which is solely or peculiarly sublime, as would necessarily be the case were magnitude itself the cause of this emotion. 2dly, That the same visible magnitude which is sublime in one subject, is frequently the reverse in another; and, 3dly, That magnitude, according to its different appearances, has different characters of sublimity corresponding to the different expressions which such appearances have; whereas, if it were itself sublime, independently of all expressions, it would, in all cases, have the same degree and the same character of sublimity.

Of outlines.

Angular durability.

Curvilinear delicacy.

Respecting the natural beauty of forms, it is stated, that matter is circumscribed, 1st, By either angular lines; or, 2dly, By curved or winding lines. When composed by one of those lines solely, they may be termed simple forms; when they are composed by an union of these lines, they may be termed complex forms. That simple forms may be described by angular or winding lines; and as so, are connected with very different associations, or are expressive of very different qualities. That the greatest part of those bodies in nature which possess hardness, durability, and strength, are distinguished by angular forms; those, on the contrary, which possess weakness, fragility, or delicacy, are distinguished by winding or curvilinear forms; and that this is evident in the mineral, vegetable, and animal kingdom; also, that those which grow and decay, are distinguished by winding forms, but maturer age by forms direct and angular. Likewise, that the sense of touch discovering angular forms to be expressive of roughness, sharpness, winding forms of softness, smoothness, delicacy, very early leave permanent impressions, and afford numerous associations, which form analogies with certain qualities of the mind, and produce some degree of the same emotion. The epithets bold, harsh, delicate, gentle, are universally applied to forms. It is concluded, that the emotions are founded upon the associated qualities, and are very different from the more agreeable or disagreeable sensations which material qualities alone convey.

Besides simple curves, there are serpentine forms, in which different curves take place, or in which a continued line winds into several curvatures, which furnishes an association of ease. When vegetables, or any other delicate body, assume their form, we are impressed with the conviction of its being easy, agreeable to their nature, and free from force or constraint. On the contrary, when such bodies, in the course of their progress, assume angular forms, we have a strong impression of the operation of force.

Nature and direction of lines.

On the subject of lines, Mr Alison makes the following important observations, which deserve the particular attention of the architect. "Lines differ either in regard to their nature or direction. 1. Lines differ in regard to their nature, according to the different degrees of their consistence and strength. Strong and vigorous lines are expressive to us of strength and stability, when perpendicular; and of some degree of harshness and roughness, when horizontal, or in an oblique direction. Fine and faint lines are expressive to us of smoothness, fineness, and delicacy. In any given number of straight lines, that is always the most beautiful which is the finest; or which, while it preserves its continuity, has the appearance of the smallest quantity of matter employed in the formation of it." But these forms are beautiful only in consequence of the associations we connect with them. Destroy that association, and they are no longer beautiful.

only beautiful from association.

Simple forms.

Ornament from the vegetable kingdom.

Delicacy.

In the course of illustrating these subjects, it is stated, that the greater part of beautiful forms in nature are formed in the vegetable kingdom; and accordingly, it is from those of the most delicate texture, that artists have selected forms to imitate, for the purpose of ornaments and elegance; but it is only those which are particularly fine and delicate which are fit for these purposes. On the contrary, the different bodies which constitute the mineral kingdom being distinguished by a greater degree of hardness and solidity, although they may be moulded into any form, yet the beauty of the serpentine form will be lost from the want of the association of delicacy; and we shall feel a discontent, from the seeming impropriety of giving such durable substances a character which does not belong to them. But there are cases, when an adventitious delicacy is given to such substances, by which the character is retained, by the form by which we have associated with them from real nature.

from dexterity of workmanship.

This effect is produced, "1st, when the quantity of matter is so small, as to overcome our opinion of its strength or durability; and, 2dly, when the workmanship is so excellent, as to produce an opinion of fineness or delicacy, independent of the nature of the subject upon which it is employed."

In architecture.

In architecture, it is observed, the great constituent parts require direct and angular lines, in order to convey the expression of stability and strength; and that no ornament can, with any propriety, be introduced, excepting in the minute and delicate parts of the work; and even, in such situations, if those ornaments exceed in size or relief that proportion in point of delicacy we expect them to hold with respect to the whole of the building, the imitation of the most beautiful vegetable forms does not preserve them from censure of clumsiness and deformity.

In further illustrating this subject, it is strongly urged, that, besides the curvilinear form, all those which are expressive of delicacy are also beautiful.

Glass lustre prism.

Such as the glass lustre, which is all angular, the form of the prism, the sword hilt, watch chain, and the forms of various jewels; which, in those hard substances, arises from their being the forms in which there is the smallest possible quantities of matter, being capable of receiving the finest polish, and producing the greatest brilliancy. But one of the most striking instances of the beauty of angular forms, is afforded in the antient tripods, in which there is the utmost possible diminution of solidity, that is consistent with convenience or use; and by its shape converging, and its dimensions lessening as they descend to the ground, there is scarcely a possibility of contriving a more angular form, or one where the slightness and apparent instability of the whole fabric can be more expressive of delicacy; and accordingly, from the principles of this delicate model, the greater part of the most beautiful articles of modern furniture are imitated.

Diminution of solidity.

Conclusions.

From the whole of this investigation respecting the beauty of natural forms, the following conclusions are drawn:—1. "That the beauty of such forms arises from the qualities of fineness, delicacy, or ease of which they are expressive.

2. That in every subject (whether angular or curvilinear) that which is the most expressive of these qualities, is the most beautiful form. And,

3. That in general, the curvilinear, or winding form, as most frequently expressive of these qualities, is the most beautiful. With regard also to those arts which are employed in the imitation or invention of ornamental forms, the following observations may not be without their use.

Delicacy and ease.

1. That wherever natural forms are imitated, those will be the most beautiful, which are most expressive of delicacy and ease.

Pleasing expression.

2. That wherever new or arbitrary forms are invented, that form will be most beautiful, which is composed of the most beautiful lines; or in other words, by lines which have the most pleasing expression. And,

Delicacy of execution.

3. That wherever the subject of the form is of a hard or durable nature, that form will be most beautiful in which the smallest quantity of matter is employed, and the greatest delicacy of execution exerted."

What has just been stated, relates to simple forms only, or to such as are described by a simple line. But as in the greater part of the beautiful forms of nature or art, lines of different descriptions unite, it is necessary to consider the composition of forms; and in doing this, it is observed, that simple forms are distinguished to the eye by the uniformity or similarity of the line by which they are described. Complex forms, by the mixture of similarity and dissimilarity in those lines, or in other words, by their uniformity and variety.

Composition of form.

Great pains are bestowed to make out distinctly, that the mere composition of uniformity and variety, or similarity and dissimilarity of form, is not in itself beautiful, but only where the objects have some general determinate character or expression, and where there is a relation among the different parts of this general character; that different proportions of uniformity and variety are required in forms of different character; that all powerful emotions, and all emotions bordering upon pain, demand uniformity and sameness; and all weak emotions, and all emotions which belong to positive pleasure, demand variety or novelty.

Painful emotions require uniformity; and those of positive pleasure, novelty.

Rules.

From the whole of the discussions, the following excellent rules are laid down.

1. "That whenever beautiful form is intended, some character or expressive form should be selected, as the ground or subject of the composition.

2. That the variety, (whether in the form, the number, or the proportion of the parts,) should be adapted to the peculiar nature of this expression, or of that emotion, which this expression is fitted to excite.

3. Forms of this kind are either simple or dependent.

In simple or independent forms, their character is at the pleasure of the artist; and that will always be the most beautiful, in which the character is best preserved.

4. In dependent forms, on the contrary, or those which are designed for particular scenes or situations, their character must be determined by that of the scene or situation; and that also will be the most beautiful form, in the composition of which the alliance to the general character is most precise and delicate."

Having discussed what relates to simple and composed forms, or what constitutes their natural beauty, the next object of consideration is the qualities which constitute their relative beauty. From the discovery of fitness or utility, we infer the existence of design. In forms distinguished by such qualities, the discovery of an end suggests intention or design; and the qualities of form, which signify this fitness or usefulness, are signs of the design or thought which produce them. But expression of design may be perceived in an object in which neither fitness or utility are to be discovered: this is evidence, "that there are certain qualities of form which are immediately and permanently expressive to us of those qualities of mind, and which derive their beauty from their expression."

Expression of design.

The natural quality most powerfully expressive of design, is uniformity or regularity. In every form where this quality is observed, we infer design; and from the absence of it, we consider the production the work of chance.

Vegetable forms, which approach to the resemblance of animals; minerals, which have a resemblance to vegetables or animals, are reckoned curious, but are never considered as possessing that beauty which excites the emotion of delight. Uniformity or regularity in rocks and mountains, is considered as a defect, and beheld only with surprise. Uniformity and regularity, therefore, are only beautiful when associated with intention or design.

Variety of embellished design.

Uniformity being expressive of design, and variety of embellished design, the beauty of forms will be most perfect when these two are duly proportioned; that is, "when the unity of design is equal, the beauty of forms will be in proportion to their embellishment; and when the embellishment is equal, their beauty will be in proportion to the unity of design."

Expressive of skill of the artist.

Character of the subject.

The qualities of uniformity and variety are beautiful from the expression of design. They are also beautiful from the effect of their composition, in maintaining and promoting the emotion which the subject itself is capable of exciting. Their composition is, in some cases, beautiful, from being expressive of the skill of the artist, and of others from being correspondent to the character or expression of the subject. The confounding of these distinct expressions, has been the cause of the greater part of the mistakes which have been made in the investigation of the beauty of these qualities.

It is of the greatest importance that the artist should pay attention to this part of the subject, because it is in his power either to sacrifice the beauty of design to that of character or expression, or the beauty of character to that of design. He ought to be fully aware of the superiority of the beauty of character or expression, in producing the greater and more affecting emotions over that of design. Also of its being more universally felt, being only dependent on our sensibility, while that of design can only be fully felt by those who are so far proficients as to judge of skill, &c.; and likewise, that the beauty of character or expression, by depending upon invariable principles of our nature, is much more permanent than that of design, which is influenced by every period of the art. It may therefore be considered a first or fundamental principle, "That the expression of design should be subject to the expression of character; and that in every form, the proportion of uniformity and variety which the artist should study, ought to be, that which is accommodated to the nature of this character, and not to the expression of his own dexterity and skill."

Expression of design subject to that of character.

Fitness constitutes relative beauty.

Fitness, or the proper adaptation of means to an end, is another source of the relative beauty of forms. In every profession, all machines, instruments, and even the most common utensils, which are well adapted to their several purposes, are, by artists, denominated beautiful. A physician talks of a beautiful theory of fevers, a surgeon of a beautiful instrument for operation, an anatomist of a beautiful subject or preparation; these instances shew, that even the objects which are most destitute of natural beauty, become beautiful when they are regarded only in the light of their fitness. Pleasing or agreeable forms receive additional beauty from being wisely adapted to some end.

"The beauty of proportion affects us with the emotion of beauty, not from any original capacity in such qualities to excite this emotion, but from their being expressive to us of the fitness of the parts to the end designed."

What we feel from observing an object which is well proportioned, is not the mere sensation of pleasure from an arrangement of parts, but an agreeable emotion from the perception of the proper disposition of these parts for an end designed.

In most familiar cases, this quality of fitness is so immediately expressed to us by the material form, that we are sensible of little difference between such judgments and the mere determination of sense; but where the object is not so familiar, or the construction is intricate, we do not discover the proportions until we have discovered the principle of the machine, or the means by which the end is attained. But if proportions consisted in any determined relation, discoverable only by a peculiar sense, the consideration of fitness could no more influence our opinions than any other consideration.

Fitness and proportion.

"Every form which is susceptible of proportion, may be considered in either one or other of the following lights. 1st, In the light of its whole or general relation to the end designed, or when it is considered as a whole, without any distinction of parts; or 2dly, In the light of the relation of its several parts to this end. Thus in the case of a machine, we may sometimes consider it in the light of its general utility for the end it is destined to serve, and sometimes in the light of the propriety of the different parts for the attainment of the end. When we consider it in the first light, it is its fitness which we properly consider; when we consider it in the second light, it is its proportion we consider. Fitness may therefore be supposed to express the general relation of propriety between means and an end; and proportion, a peculiar or subordinate relation of this kind, viz. the proper relation of parts to an end. Both agree in expressing the relation of propriety between means and their ends. Fitness expresses the proper relation of the whole of the means to the end; proportion, the proper relation of a part or parts to their ends."

Forms are susceptible of as many determinate proportions, as they are susceptible of parts necessary for the end for which they are intended. If they have any more parts, these are not susceptible of any accurate proportions, and are accordingly constantly varying; and we are only sensible of the proportion of forms, as we become acquainted with the fitness of its construction. Of a new machine, with which we are unacquainted, we cannot decide of the propriety or impropriety of its proportions. The more extensive our knowledge is of the fitness of the forms for their several ends, the better we shall be qualified to judge of the propriety of their several proportions; "and in general it may be observed, that the certainty of proportion is, in all cases, dependent upon the certainty of fitness. 1st, When this fitness is absolutely determined, as in many cases of mechanics, the proportion is equally determined. 2d, Where it is determined only by experience, the opinion of the beauty of proportion varies with the progress of such experience. 3d, Where this fitness cannot be subjected to experience, as in the case of natural forms, the common proportion is generally conceived to be fittest, and is therefore considered as the most beautiful." In following the author through the foregoing discussions, we have merely endeavoured to preserve the connection of his general principles, neglecting most of his beautiful illustrations, and avoiding, as much as possible, the numerous application of his principles to the theory and practice of the other fine arts, our object being only to trace what was necessary to determine the principles of architecture. We presume the reader, who has with attention accompanied us this far, will already have discovered more rational grounds for general principles, than has been furnished by any other author. We are now to proceed to consider the merits of his application of the foregoing principles more immediately to the art of architecture.

General reflections.

Principles applied to architecture.

After remarking, that former writers have been unanimous in considering proportions as deriving their effects from the original constitution of our nature,—and that they have endeavoured to support this opinion by analogies drawn from proportions in music and numbers,—and remarking, that all reasonings from such analogies are too futile to require any attention,—Mr Alison proceeds to show, that the beauty of the proportions of this art is resolvable into the principles which have been established, and that they please us not from any original law of our nature, but as expressive of fitness. The proportions of architecture relate either to its external or internal members. The beauty of external proportions, we are informed, arises from their apparent fitness for the habitations of men when viewed from without, and consists in stability and sufficiency for the support of the roof; walls in every country, in the same period of time, are nearly of an equal thickness for their stability, and to the support of any weight laid upon them; and when their distance from each other is suitable, the building is considered as well proportioned; but when the walls are so thin or high, or placed at so great a distance from each other, as to appear insecure of themselves, or insufficient to support the roof, that building is reckoned to be ill proportioned. Proportion therefore, in those cases, is merely fitness, and this has never been very precisely determined; we are here guided entirely by experience, and our sentiments respecting proportions are influenced by the nature of the buildings, and the materials of which they are composed. Edifices constructed with wood or brick, admit not of the walls being equally high as if built of stone. A house united with others, may be carried higher than if placed alone. A tower or spire having only itself to support, may with propriety be carried to a much greater height than any other species of building. These principles are all that seem to regulate the external proportions of simple buildings, and all of them obviously depend upon fitness.

Proportions please from an expression of fitness.

Principles applied to the orders of architecture.

Having discussed what relates to the proportion or fitness of the general outlines of buildings, Mr Alison proceeds to treat of the orders of architecture, and to show, that their proportions, instead of being intrinsically beautiful of themselves, are regulated by the general principles which have been established in this essay, and derive their merit solely from the expressions of fitness for their several purposes. But as this important part of the discussion overthrows established opinions, which have a peculiarly strong possession of the minds of all those who have paid attention to or are engaged in architectural pursuits, we shall quote the precise words of the author:

"It is not in such (simple) buildings, accordingly, that any very accurate external proportions have ever been settled. This is peculiar to what are called the orders of architecture, in which the whole genius of the art has been displayed, and in which the proportions are settled with a certainty, so absolute, as to forbid almost the attempt at innovation.

"There are generally said to be five orders of architecture, viz. the Tuscan, the Doric, the Ionic, the Corinthian, and the Composite. These are, however, properly only four, and some writers have farther reduced them to three. What constitutes an order, is its proportions, not its ornaments. The Composite having the same proportions as the Corinthian, though very different in respect to its ornaments, is properly, therefore, considered a corrupted Corinthian.

Composition of order.

"Every order consists of three great parts, or divisions; the base, the column, and the entablature; and the governing proportions relate to this division. The whole of them compose the wall, or what answers to the wall of a common building, and supports the roof.

Difference between order and wall.

"There is one great difference, however, to be observed between a common wall, and that assemblage of parts which constitute an order. A common wall is intended to support a roof, and derives its proportions, in a great measure, from this destination. To an order, the consideration of a roof is unnecessary; it is generally so contrived as not to appear: the weight which is supported, or appears to be supported, in an order, is the entablature. The fitness of a wall consists in appearing adequate to the support of the roof. The fitness of an order, or of the proportions of an order, it should seem also from analogy reasonable to conclude, consists in their appearing adequate to the support of the entablature, or the weight which is imposed on them.

Beauty arises from fitness.

"That this is really the case, and that it is from their being expressive to us of this fitness, that the proportions of these different orders appear beautiful, may perhaps seem probable from the following observations:

"1. The appearance of these proportions themselves seems very naturally to lead us to this conclusion. In all the orders, the fitness of the parts to the support of the peculiar weight, or appearance of weight of entablature, is apparent to every person, and constitutes an undoubted part of the pleasure we receive from them. In the Tuscan, where the entablature is heavier than in the rest, the column and base are proportionably stronger. In the Corinthian, where the entablature is lightest, the column and base are proportionably slighter. In the Doric and Ionic, which are between these extremes, the forms of the column and base are, in the same manner, proportioned to the reciprocal weights of their entablatures; being neither so strong as the one, nor so slight as the other. If the beauty of such proportions is altogether independent of fitness, and derived from the immediate constitution of our nature, it is difficult to account for this coincidence; and as the beauty of fitness, in these several cases, is universally allowed, it is altogether unphilosophical to substitute other causes of the same effect, until the insufficiency of this is clearly pointed out.

Illustration.

2. "The language of mankind upon this subject, seems to confirm the same opinion. Whenever we either speak or think of the proportions of these different orders, the circumstances of weight and support enter both into our consideration and our expression. The term proportion, in its general acceptation, implies them; and if this term is not used, the same idea, and the same pleasure, may be communicated by terms expressive of the fitness for support of weight. Heaviness and slightness, or insufficiency, are the terms most generally used to express a deviation on either side from the proper relation; both of them obviously including the consideration of support, and expressing the want of proportion. When it is said, that a base, or column, or entablature, is disproportioned, it is the same thing as saying, that this part is unfitted to the rest, and inadequate to the proper end of the building. When it is said, on the other hand, that all the several parts are properly adjusted to their end, that the base appears just sufficient for the support of the column, and both for that of the entablature, every person immediately concludes, that the parts are perfectly proportioned; and I apprehend, it is very possible to give a man a very perfect conception of the beauty of these proportions, and to make him feel it in the strongest manner, without ever mentioning to him the name of proportion, merely by explaining them to

Heaviness.
Slightness.

Unfitness.

him under the consideration of fitness; and by showing him, from example, that these forms are the most proper which can be devised for the end to which they are destined. If our perception of the beauty of proportion, in such cases, were altogether independent of any such considerations, I think that these circumstances in language could not possibly take place, and that it would be as possible to explain the nature and beauty of proportions by terms expressive of sound or colour, as by terms expressive of fitness or propriety.

Ideas of proportion acquired.

3. "The natural sentiments of mankind on this subject, seem to have a different progress from what they could naturally have, if there were any absolute beauty in such proportions discoverable by the eye. It cannot surely be imagined, that an infant will perceive, or does perceive, the beauty of such proportions, in the same manner as he perceives the object of any other external sense. It is not found either, that the generality of mankind, even when come to mature age, express any sense of the absolute beauty of such objects. It is true indeed, that, very early in life, we are sensible of disproportion in building; because the ideas of bulk and support are so early and so necessarily acquired; and the eye is so soon habituated to judge of weight from visible figure, that what is fit for the support of weight is very soon generally ascertained. What a common person, therefore, expresses upon the view of such proportions, is rather satisfaction than delight. It is not the proportions which most affect him; it is the magnificence, the grandeur, and costliness, which such buildings usually display; and though he is much pleased with such expressions, he is generally silent with regard to the beauty of those proportions with which the connoisseurs are so much enraptured. If proportion, on the contrary, were something absolutely beautiful, in such objects the progress of taste would be reversed; the admiration of the infant would be given to those proportions, long before he was able to judge of their fitness; and the satisfaction which arises from the expression of fitness would be the last ingredient in his pleasure, instead of being, as it now is, the first.

Dependent upon fitness.

4. "The nature of these proportions themselves, seems very strongly to indicate their dependence upon the expression of fitness. The beauty of such forms (on the supposition of their absolute and independent beauty,) must consist either in their beauty, considered as individual objects, or in their relation to each other. If the effect arises from the nature of the individual forms, then it must obviously follow, that such forms or proportions must be beautiful in all cases. I think, however, there is no reason to believe this to be the case; the base of a column, for instance, (taken by itself, and independent of its ornaments, which in this enquiry are entirely excluded from consideration,) is not a more beautiful form than many others that may be given to the same quality of matter. The peculiar form which its proportions give to it, is very far from being beautiful in every other case, as would necessarily happen, if it were beautiful in itself, and independent of every expression. A plain stone, of the same magnitude, may surely be carved into very different forms, from those which constitute the bases of many of the orders, and may still be beautiful. In the same manner, the column (considered as in the former case, merely in relation to its peculiar form, and independent of its ornaments,) is not more beautiful, as a form, and perhaps not so beautiful, as many other forms of a similar kind. The trunk of many trees, the mast of a ship, the long slender Gothic column, and many other similar objects, are to the full as beautiful, when considered merely as forms, without any relation to end, as any of the columns in Greek architecture. If, on the contrary, these forms were beautiful in themselves, and as individual objects, no other similar forms could be equally beautiful, but such as had the same proportions. The same observations will apply equally to the form of the entablature. It would appear, therefore, that it is not from any absolute beauty in these forms, considered individually, that our opinion of their beauty in composition arises. If it is said, on the other hand, that the beauty of proportion in such cases, arises in relation of these parts, and that there is something in the relations of these forms and magnitude, in itself beautiful, independent of any consideration of fitness, there seem to be equal difficulties. Besides the relation of fitness for the support of the weights, the only relations which take place among these parts, are the relations of length and breadth, and the relation of magnitude. If this beauty arises from the relation of length, it is necessary to shew, that such a proportion of these parts, in point of length, is solely and permanently beautiful. If from the relation of breadth, there is the same necessity of showing, that such a proportion of these is point of breadth is permanently beautiful. If from both together, then the same proportion only ought to be felt as beautiful, in all cases to which the relations of length and breadth can apply. If again, this beauty arise from the relation of magnitude, it is necessary, in the same manner, to shew that their magnitudes or quantities of matter, have in fact no other beautiful proportions, but those which takes place in such order; but as it is very obvious, that there is no foundation for supposing there is any such law in our nature, and that, on the contrary, in innumerable cases of all such relations, different and contrary proportions are beautiful; it cannot be supposed that such proportions are absolutely beautiful from any of these relations. The only relation, therefore, that remains, is the relation of fitness, and if the same inquiry is carried on, I believe it will soon be found, that a certain proportion of parts is necessarily demanded by this relation, and very probably also, that this certain proportion, is in fact, in each of these orders, according to the particular weight or bulk given.

Experience discovers fitness.

"If an order is considered as an assemblage of weight, and parts to support that weight, our experience immediately leads us to conceive a proper relation of those parts to their end. If the entablature be considered as the weight, then of course a certain form and size in the column is demanded for the support of it, and in the base for the support of both. A plain stone, for instance, set on its end, has no proportion, further than for the purpose of stability. If it appears firm, it has all the proportions we desire or demand; and its form may be varied in a thousand ways, without interfering with our sense of its proportions. Place a column, or any other weight, upon this stone, immediately another proportion is demanded, viz. its proportion to the support of this weight. The form supported has, however, no proportion further than is necessary for its stability. It may be more or less beautiful in point of form from other considerations, but not on account of its proportions. Above this again place an additional body, 'immediately the intermediate form demands a new proportion, viz. to the weight it supports;' and the first, or base, demands also another proportion, in consideration of the additional weight which is thus imposed upon it. In this supposition, it is obvious, that the consideration of fitness alone leads us to expect a certain proportion among each of these parts. The parts are beautiful or pleasing just as they answer to this demand; and where the parts are few, and experiments easy, it seems not difficult at last to arrive at that perfect proportion which satisfies the eye as sufficient for the purposes of support and stability. If we leave, therefore, every thing else out of consideration, the consideration of fitness alone seems sufficient to account both for the origin of such proportions in architecture, and for the pleasure which attends the observation of them."

But granting that the doctrine of the original beauty of proportion be abandoned as inconsistent with experience, and that of the influence of the expression of fitness adopted, yet it may still be doubted if this is sufficient to account for the delight felt from the orders of architecture, or the uniform adherence to the established proportions.

Mere fitness insufficient.

"It is acknowledged, that the mere consideration of fitness is insufficient to account for the pleasure derived from the established orders. But it is observed, that this pleasure arises from very different causes than from their proportions; and that, in fact, when these proportions only are considered, the pleasure which is generally felt is not greater than that which we experience, when we perceive in any great work the proper relation of means to an end.

"The proportions of these orders, it is to be remembered, are distinct subjects of beauty, from the ornaments with which they are embellished, from the magnificence with which they are executed, from the purposes of elegance they are intended to serve, or the scenes of grandeur they are destined to adorn. It is in such scenes, however, and with such additions, that we are accustomed to observe them; and while we feel the effects of all these accidental associations, we are seldom willing to examine what are the causes of the complex emotion we feel, and readily attribute to the nature of architecture itself the whole pleasure which we enjoy. But besides these, there are other associations we have with these forms, that still more powerfully serve to command our admiration, for they are the *Grecian* orders; they derive their origin from those times, and were the ornament of those countries which are most hallowed in our imaginations; and it is difficult for us to see them, even in our modern copies, without feeling them to operate upon our minds as relics of those polished nations where they first arose, and of that greater people by whom they were borrowed. While this species of architecture is attended with so many and so pleasing associations, it is difficult for even a man of reflection to distinguish between the different sources of this emotion; or in the moments when this delight is felt, to ascertain what is the exact proportion of his pleasure, which is to be attributed to these proportions alone; and two different causes combine to lead us to attribute to the style of architecture itself, the beauty which arises from many other associations."

Accidental associations.

Material sign of affecting qualities.

In the first place, while this architecture is under our eye, it is the central object of all those associations, it is the material sign of all the affecting qualities, and disposes us to attribute to the sign the effects which are produced by the qualities signified. And even these very proportions are the cause of our pleasure, because they are the only qualities of the object which are accurately ascertained; they have long been the acknowledged objects of beauty, and having got possession of one undoubted principle, we are easily induced to ascribe the whole effect to this principle alone.

Common people. Men of letters. Artists. Dimensions.

That this is really the case, will appear evident, by considering that the common people feel a very inferior emotion of beauty from such objects, to that which is felt by men of liberal education; the man of letters feels also a weaker emotion than a well-educated architect, because he has none of the associations which belong to the art, and never considers them in relation to the skill or invention they display. Deprive these orders of the customary ornaments, or change only, in the slightest degree, their forms, without altering their proportions, and their beauty will be in a great measure destroyed; or preserve the ornaments, forms, and proportions, but diminish them to a small scale, and their effect will be much inferior to what they produce, when executed on the magnificent scale of the antient temples; or destroy the associations of elegance, magnificence, costliness, but, above all, of antiquity; and it must appear evident, that the pleasure which these proportions would afford, would not be greater than that which we feel in other cases, when means are properly adapted to their end.

Antiquity. Costliness.

In regard to the observation, that the universal adherence of mankind to these proportions is a sufficient proof of their absolute beauty, it is necessary to remark, that the associations of antiquity alone, have a powerful effect in producing uniformity of opinion; also, that in the productions of human labour, the influence of variety is limited by the costliness and durability of the materials upon which that labour is employed; where they are very costly, the objects have great intrinsic value, independent of any particular form; and the same form is therefore adhered to with little variation. Even in dress, it is in the parts the least costly that the most frequent changes take place. Architecture is of all the fine arts the most costly; the revenue of nations is scarcely sufficient to defray the expence of frequent productions of its most magnificent forms; and the art itself, after it has arrived at a certain necessary degree of perfection, remains in a great measure stationary, both from the infrequency of cases in which invention can be employed, and from the little demand there is for the exercise of this invention.

Durations.

The objects upon which this art is employed, besides being costly, are also very durable. Centuries must probably pass before they are renewed, and during that time, the sacredness of antiquity is acquired by the subject itself, and likewise a strong motive for the preservation of similar forms.

The foregoing observations relate wholly to the external parts of architecture. It is therefore necessary to consider, whether the Internal Proportions are guided by the same principles.

Internal proportions.

Internal proportions arise from the disposition of length, breadth, and height, so as to render an apartment pleasing in its forms; and certain proportions of these dimensions have been held as beautiful in themselves, from the original constitution of our nature, and independent of any expression; but, agreeably to the principles established in this Essay, the beauty of their proportion arises from the expression of fitness.

A plain wall is only capable of that proportion of height which is necessary for the expression of strength and stability. This is all we desire; it is also, of course, Walls to support the roof.

applicable to four walls inclosing a space. But add a roof to this inclosure, and other proportions are demanded, in consideration of the apparent weight which is to be supported. If the walls are too high, they seem insufficient for the weight; if too low, the roof appears unnecessarily heavy; and if the length is too great, the weight of the roof, by the perspective, appears to become too great as it retires; if the breadth is too great, there is an apparent insufficiency created by the too great distance of the walls: Certain proportions, therefore, in length, breadth, and height, fitted for the full and easy support of the roof, are required. If these are accomplished, we require no more; and if they are not accomplished, every person is sensible of the defect. It therefore follows, that these proportions are beautiful, from being expressive of fitness. The real beauty of the internal proportions of architecture is not, to the bulk of mankind, greater than what attends the expressions of fitness; it is satisfaction rather than positive delight. In apartments where this proportion has been studied, it is with the convenience, furniture, decorations, or magnificence, we are delighted. With the mere outlines of the best proportioned, but unfinished, room, we have only the same moderate pleasure which we receive from observing a well-constructed machine. "If, therefore, certain proportions are demanded in a room as expressive of fitness, and if the emotion that is produced by the established and regular proportions is no greater than that which we receive in other cases; from the expression of this quality, it seems reasonable to think, that these proportions are in fact beautiful, from the expressions of this fitness." The common language of men confirms these statements: they express their sense of proportions by too high or too low, by being heavy or light; and in explaining to them the nature of internal proportions, we should do it by pointing out, that the walls were well fitted or adapted to support the weight; or that they were too high, or too low, or too distant, or that the roof was heavy or light; but this might, and most probably would, all be done, without even mentioning proportions, but referring to the expressions of fitness.

The progress of taste is also decisive upon this subject. If proportions were originally beautiful, the early period of life would be remarkable for the discovery of them; but every one is sensible, that it is only after we have, from experience, acquired a knowledge of the relation between weight and support, that we are sensible of proportions. If there were any absolute and independent beauty in forms, every violation of them would be equally painful; but it is evident that this is not the case: too great a height or length in any apartment, is not so disagreeable as too great a breadth, or being too low. No uniform emotion, therefore, attending the perception of these proportions, as would necessarily be the case if their beauty were perceived by any peculiar sense, and the emotions which we receive from them being different according to their different expressions of fitness, it seems reasonable to ascribe their beauty to this expression, and not to any original beauty in the proportions themselves. If there were any original beauty in such proportions, they would be as certain as those of any other sense; there would be one precise proportion of these dimensions, of length, breadth, and height, solely and permanently beautiful. But no artist has pretended to determine any such proportions; on the contrary, there is no permanent beauty in any one relation of those dimensions; the same proportions which are beautiful in one apartment, are not so in another.

Causes of difference of opinion.

There appear to be three causes for the difference of our opinions of proportions: 1st, From the consideration of the weight supported. As roofs are usually composed of timber, and supported by walls, the necessary dimensions are not very precisely determined; and they may, accordingly, be varied within certain limits. These limits are less rigorous in the case of length or height, than in what regards breadth; for the same proportion of breadth which is beautiful in one case, would be positively disagreeable in another.

Character of apartment.

Require different proportions.

2d, The difference of opinion arises also from the character of the apartment, as gaiety, simplicity, solemnity, grandeur, magnificence; for no room is beautiful which has not some expressive character. The same proportion which is beautiful in a room of gaiety, would be a defect in one whose character was that of simplicity; the same proportions which are pleasing in an elegant or convenient room, would be defective in an apartment of magnificence and splendour. In general, the great and positive beauty of apartments arises from their character; thus difference of character requires a difference in the composition of the dimensions, and a beautiful form is only produced, when the composition of different proportions is such as to produce one pure and unmingled expression.

3. A third cause of the difference of our opinions of the beauty of proportions, arises from the destination of the apartment; and this, as in the hall, saloon, antichamber, drawing-room, dining-room, library, chapel, &c. requires different proportions, and these depend jointly upon utility and character.

Kinds of fitness.

The observations offered on the beauty of the internal proportions of architecture, afford sufficient evidence for concluding, in general, that the beauty of these proportions is not original and independent, but that it arises in all cases from the expression of some species of fitness. The fitness which such proportion may express, is of different kinds; as,

"1. One beauty of these proportions arises from their expression of fitness for the support of the weight imposed.

"2. A second source of their beauty consists in their expression of fitness for the preservation of the character of the apartment.

"3. A third source of their beauty consists in their expression of fitness, in the general form, for its peculiar purpose or end.

"The two first constitute the permanent beauty, and the third the accidental beauty of an apartment.

Permanent beauty.

"The most perfect beauty that the proportions of an apartment can exhibit, will be when all these expressions unite, or when the same relations of dimensions which are productive of the expressions of sufficiency, agree also in the preservation of character, and in the indication of use."

Accidental beauty.

Besides the expressions that have now been considered as great and permanent sources of the beauty of forms, there are others which have an observable effect in producing the same emotion in our minds, which may be termed accidental beauty.

Associations of this kind arise from education, from early or peculiar habits of thought, from situation, and from professions; and the beauty they produce is felt only by those whom similar causes have led to the formation of similar associations. When these associations are common to many individuals, they sometimes become superior to the more permanent principles of beauty, and may for a time determine the taste of nations.

Fashions in furniture.

The succession of the fashions of furniture, is a strong instance of this. Within a few years, the forms copied from the Chinese, the Gothic, and Antique styles, have succeeded each other; and each, in its turn, has been cultivated with equal zeal and success. With the first, were associated all the notions of eastern magnificence; with the second, the adventures and gallantry of the Gothic manners, and all the elegance and splendour of its cathedrals; and, with the third, our imaginations are crowded with the recollection of Grecian and Roman taste.

Conclusions.

From the whole of the foregoing discussions and illustrations, the following conclusions are drawn:

" That the principal sources of the beauty of forms are, 1st, The expression which we connect with peculiar forms, either from the form itself, or the nature of the subject formed. 2dly, The qualities of design, and fitness, and utility, which they indicate; and, 3dly, The accidental associations which we happen to connect with them.

All forms are either ornamental or useful.

I. The beauty of merely ornamental forms appears to arise from three sources:

1. The expression of the form itself.
2. The expression of design.
3. Accidental expression.

" The real and positive beauty, therefore, of every ornamental form, will be in proportion to the nature and the permanence of the expression by which it is distinguished. The strongest and most permanent emotion, however, we can receive from such expressions, is that which arises from the nature of the form itself. The emotion we receive from the expression of design, is neither so strong nor so permanent, and that which accidental associations produce, perishes often with the year which gave it birth. The beauty of accidental expression is as variable as the caprice or fancy of mankind. The beauty of expression of design varies with every period of the art. The beauty which arises from the form itself, is alone permanent, as founded on the uniform constitution of the human mind. Considering, therefore, the beauty of forms, as constituted by the degree and permanence of their expression, the following conclusions seem immediately to suggest themselves.

1. That the greatest beauty which ornamental forms can receive, will be that which arises from the expression of the form itself.
2. That the next will be that which arises from the expression of design or skill. And,
3. That the least will be that which arises from accidental or temporary expression.

Accidental associations to be sacrificed to permanent expression.

In all those arts, therefore, that respect the beauty of form, it ought to be the unceasing study of the artist to disengage his mind from the accidental associations of his age, as well as the common prejudices of his art, to labour to distinguish his productions by that pure and permanent expression, which may be felt in every age, and to disdain to borrow a transitory fame, by yielding to the temporary caprices of his time, or by exhibiting only the display of his own dexterity and skill."

We conceive that the reader who has attentively considered even this slight sketch of Mr Alison's valuable investigations, will agree with us, that the true principles of architecture have at last been distinctly established; and that the liberal-minded artist will perceive with pleasure, that, instead of being left, as formerly, entangled in uncertainty and confusion, the path to correct practice in his profession is now precisely marked out, and that all his operations are guided by principles as invariable as the constitution of the human mind.

Architecture susceptible of expressions;

From the principles here laid down, it follows, that architecture, as well as sculpture and painting, is perfectly susceptible of distinct expressions of character; that this character may and ought to accord with the situation and purposes for which the edifice is destined; and that all the component parts should tend to promote a full and distinct expression of the general character. For can any thing be more absurd, than to see an edifice appropriated to the sacred purposes of divine worship, composed of a variety of trifling parts, disfigured by gaudy decorations, and neither externally nor internally possessing features expressive of its true character; or, to see what is too frequently met with in buildings appropriated to the most ordinary purposes of life, puny imitations of those forms which ought only to be introduced, of suitable dimensions, in works of magnificence and sublimity; or to find, mixed in the same edifice, forms of expression so opposite as to distract the mind, and completely destroy the intended effect.

frequently violated.

Observations by Professor Stewart.

The following judicious observations of Professor Stewart will account distinctly for the incongruities and bad taste which have occasionally overspread every country in every school of architecture, and which must continue to be the case, unless mankind will benefit by the errors of their predecessors, and be contented to guide their conduct upon true principles. " From the account which has been given of the natural progress of taste, in separating the genuine principles of beauty from the superfluous and offensive concomitants, it is evident there is a limit beyond which the love of simplicity cannot be carried; no bounds indeed can be set to the creations of genius, but as this quality occurs seldom in an eminent degree, it commonly happens, that after a period of great refinement of taste, men begin to gratify their love of variety, by adding superfluous circumstances to the finished models exhibited by their predecessors, or by making other trifling alterations on them, with a view of merely diversifying the effect. These additions and alterations, indifferent perhaps, or even in some degree offensive in themselves, acquire soon a borrowed beauty, from the connexion in which we see them, or from the influence of fashion; the same cause which at first produced them, continues perpetually to increase their number, and taste returns to barbarism, by almost the same steps which conducted it to perfection." (See *Elements of the Philosophy of the Human Mind*, 3d edit. 8vo, p. 373.) But, instead of contemplating the prospect of degeneracy in architecture, may we not hope, by the general dissemination of true principles, to witness a progressive improvement, agreeably to the views taken by the same able and profound philosopher, in page 460 of his *Phil. Essays?*—" The history of taste will be found analogous to that of human reason, the taste of each successive age, being formed on the study of more perfect models than that of the age before it, and leaving in its turn to after times a more elevated ground-work on which they may raise their own superstructure.

Progress of bad taste.

Progress of good taste.

" This traditionary taste (imbibed in early life, partly from the received rules of critics, and partly from the study of approved models of excellence,) is all that the bulk of men aspire to, and perhaps all that they are qualified to acquire. But it is the province of a leading mind to outstrip its cotemporaries, by instituting new experiments for its improvement; and in proportion as the observations and experience of the race are enlarged, the means are facilitated of accomplishing such combinations with success, by the multiplication of those selected materials out of which they are to be formed.

"In individuals of this description, taste includes genius as one of its elements; as genius, in any of the fine arts, necessarily implies a certain portion of taste. In both cases, precepts and models, although of inestimable value, leave much to be done by an inventive imagination.

"In the mind of a man who feels and judges for himself, a large proportion of the rules which guide his decisions, exist only in his own understanding. Many of them he never thought of clothing in language even to himself, and some of them would certainly, if he should attempt to embody them in words, elude all his efforts to convey their import to others."

Such are the views we indulge of the future progress of all human attainments; and as the habits of man would change with his improved condition, there would, in every succeeding age, be still sufficient opportunities for the ingenious architect to exercise cultivated taste and original genius, under the influence of the same unvarying and unerring principles.

Newton's Vitruvius

Besides the authorities already produced, we may further state, that Newton, in the preface to his translation of *Vitruvius*, page vii. says, "I imagine every building should by its appearance express its destination and purpose, and that some character should prevail therein, which is suitable to, and expressive of, the particular end it is to answer; to effect this will require the exertion of the powers of the mind, the force of genius, and solidity of judgment; and without this, a composition is but a compilation of parts, without meaning or end." And again, page viii. "The character or effects which there may be occasion to express in buildings, may be distinguished into the pleasing and elevating, or those of beauty and dignity; the several characters of each class might be ascertained, as well as the kinds and degrees of the sensible properties that will produce the appearance of each character; but it would carry me farther than I intend in this preface, in which I only mean to give a general sketch of my sentiments on this matter, in order to shew the opening there seems to be for a full disquisition of the subject, and the possibility of bringing the art of designing architecture (which at present has no guide but fancy and habit) to some regulation and certainty."

Knight on Taste.

Mr Knight, in his book on Taste, p. 172, says, "that fitness depends upon the association of ideas, and symmetry more so." And again, p. 182, "that imitators err in copying effects instead of studying and adopting principles, disregarding all those local, temporary, or accidental circumstances, upon which their propriety or impropriety, their congruity or incongruity depends; which principles in art are no other than the trains of ideas which arise in the minds of the artist, out of a just and adequate consideration of all such circumstances, and direct him in adapting his work to the purposes for which it was intended; consequently, if either of those circumstances or purposes change, his ideas must change with them, or his principles will be false, and his works incongruous."

Illustrations.

Both Newton and Knight confirm the doctrine of association; but it is Mr Alison alone who explains distinctly the means by which we are to determine and attain the various characters which it is necessary to establish. The attentive artist, by studying what has been said respecting colour and form, but more especially the latter, will be enabled to select features suitable to the character of his edifice. He will perceive that large, square, angular forms, composed of straight outlines, are expressive of power, harshness, strength, and durability, and that such are found in the temples, palaces, pyramids, and gigantic statues of Upper Egypt; also in the bold projecting porticos of the rectangular temples of Greece, placed upon broad platforms, and consisting of strongly marked parts.

Power.

Durability.

Gaiety.

It will also be evident, that slender, curved, and winding lines are expressive of gaiety and lightness: to exemplify this, we may mention the whole of tent architecture, also a great portion of the decorations of ceiling, friezes, and pannels, whether executed in sculpture, stucco, or painting. The tripod form, also, by diminishing in dimensions towards the base, is expressive of the reverse of weight and stability.

In decorative sculpture, both these distinctions are strongly marked; the first by the bold and square outlines in the statues of Olympian Jupiter, and the last by the delicate flowing outlines of Greek statues of fauns, nymphs, and graces.

Richness.

Richness will be expressed by the value of the materials, and the quantity and dexterity of labour bestowed upon them. As it is not in modern Europe the custom in architecture to work much in metals, it has therefore been by marbles, highly polished and dexterously sculptured, that this art has been chiefly enriched. But in former times, when metal was introduced amongst the ancient Romans, and the later Eastern nations, and as it is at present in chimneys, it is the quantity of labour and art bestowed upon nice cutting, high polishing, and delicate engravings, which commands our admiration. Even materials less costly are converted into objects of regard, by the hand of art being liberally bestowed upon them. For we see that sandstone and stucco, by being formed into sculptured mouldings, highly worked Guilochi and fret-work, become expressive of richness. And nothing of this sort is a more convincing proof of the truth of the doctrine of association, than the indenting or inlaying of different kinds of woods and marbles, which are always valued in proportion to their rarity, and the quantity and dexterity of labour bestowed upon them; and their particular character is determined by the shape and substance of the forms into which they are disposed.

Sublimity.

Sublimity is strongly exemplified in the lofty dome, spire, and embattled tower; and these, besides the associations of the expense, power, and design necessary in their construction, have our veneration increased by their antiquity, and appropriation to the purposes of religion and war.

Conclusion.

These slight observations, with the recollection of what has already been said of the relative beauty of fitness and utility, will lead the reader, interested in such speculations, to pursue the subject to a greater length than can be afforded in a work of this nature. He will be at no loss to select abundance of examples from works in every school of architecture; and by duly appreciating the principles here laid down, he will be enabled to produce original designs, which cannot fail of commanding the admiration of mankind.

PART III. PRACTICE OF ARCHITECTURE.

Practice.

IN treating of the practice of architecture, we shall, as nearly as circumstances admit, pursue the same track which we have followed in its history.

General remarks.

In what regards the ancient works of Egypt, India, and Persia, no certain account of the modes adopted in constructing them having reached modern times, we are only enabled to give some account of the general forms and constituent parts of public edifices which now exist, or have been described; leaving the reader, from these data, and the circumstances connected with their situation and history, to draw his own conclusions. What relates to Chinese, Greek, and Roman edifices, is more abundant; and that of the more recent and present ages, as it is to us the most important, will likewise be found the most ample.

EGYPTIAN ARCHITECTURE.

Egypt.

Tapering walls. Huge pillars. Fine sandstone; some calcareous; seldom granite.

Columns bundles of lotus.

Egyptians did not copy others.

Modified.

In the practice of architecture, Upper Egypt appears to have borrowed nothing from any other nation: it is the result of a powerful people attaining their objects by the simplest means. Their most ancient buildings are composed merely of tapering walls, with pillars of huge dimensions placed in the intermediate spaces, to support a roof constructed with large flat stones, all of the kind of stone found in the immediate neighbourhood; that is to say, in a few instances of calcareous, but chiefly of fine sandstone; for, as we have formerly remarked, it was not until after the translation of the empire to Thebes, that granite was employed, excepting in obelisks and colossal statues. The workmanship of Karnac and others of the ancient buildings, has also a rudeness which bespeaks an infancy of the arts. Yet even in this earliest stage, the columns are representations of bundles of the lotus (or lily of the Nile): and the sculptured hieroglyphics are wholly taken from Egyptian mythology, astronomy, historical events, and agriculture; they have evidently arisen from the peculiar situation and circumstances of that particular people; and so far were the Egyptians from being influenced by the practice of the neighbouring nations, that the outlines of the façades and sculptures found in their apparently oldest temples were, with some improvement in the workmanship, preserved nearly the same, till the destructive inroad of Cambyses.

Thebes.

Palace and temple united.

In our historical sketch, the principal circumstances relating to Karnac, Luxor, and the Memnonium, were briefly described: These, from the nature of the sculptures and distribution of the apartments, have by some been supposed to have been royal edifices. At all other places, the ancient buildings are considered as having been appropriated to religious purposes. But, from the accounts handed down respecting the nature of the authority exercised by the Egyptian priesthood, it is probable that even at Thebes the palace and temple were united. We shall therefore proceed to mention the principal dimensions and features of the most noted of these ancient buildings, and introduce such observations as, with the aid of the annexed Plates, will enable the reader to form a tolerably distinct idea of their mode of construction and appropriation.

Practice.

Tentyra. PLATE CXLVIII.

Dimensions of the temple of Isis.

Zodiac.

Capitals heads of Isis. PLATE CL. Fig. 2.

Sanctuary.

Staircase.

Zodiac on terrace or roofs.

TENTYRA, (see Plate CXLVIII.) which contained the most perfectly executed of the Egyptian temples, is situated upon the Lybian shore of the Nile, at the distance of about half a league from the river. The principal temple was consecrated to Isis. The façade is 72 paces in breadth, 145 in depth, and 70 feet in height. A doorway, of elegant form and workmanship, conducts into a portico 60 paces by 30, supported by 24 columns, seven feet diameter, and 55 in height. This portico has zodiacs painted on the ceiling. The hall, which succeeds the portico, is 24 paces square. It is supported by six columns, whose capitals are each composed of four figures of the head of Isis with the ears of a cat (See Plate CL. Fig. 2.); the second hall is 24 paces by 10; the third is of the same dimensions. The apartment which succeeds the last hall is 24 paces by 6, and is insulated by a space on each side of it; this is probably the sanctuary. In the before mentioned second hall, there are two staircases, which lead to the terrace or roof; the steps are each 20 inches broad, and 2 inches high; upon this terrace there is a small apartment 9 feet square, having a very full and perfect zodiac painted on the ceiling. In one of the interior courts of the temple, there is a zodiac which occupies one half of the ceiling of the last mentioned hall, which seems entirely devoted to astronomy; the zodiac is divided from another astronomical picture by the figure of a woman. Behind this great temple is a small one, also consecrated to Isis; it is about 17 paces square. To the right of the door of the great temple, is a periptere temple about 34 paces square, dedicated to Typhon: Fifty paces from the north door is another periptere temple, which appears never to have been finished.

Apollinopolis.

Description.

Length.

In the temple at APOLLINOPOLIS (or Edfou), which, next to Thebes, is the largest edifice in Upper Egypt, the two moles at the entrance are nearly in contact; the doorway is higher than in any other temple; it opens into a vast court, surrounded by columns, in form of a peristyle; the lodging for the priests were behind the peristyle. The portico is formed of six columns in front, and three deep; some of the capitals have three rows of leaves approaching to the Corinthian. The interior distribution is similar to Tentyra. This edifice is 500 feet in length, and is constructed of fine sandstone.

PLATE CXLVIII.

The entrance to Latopolis, as will be seen, (Plate CXLVIII.), is exceedingly fine. It consists of 24 elegant columns, whose capitals vary as to decoration, but are each of masterly execution; being an evidence of the improved state of sculpture; and that, if unfettered by monastic regulations, the artists would have risen to superior excellence. It is also worthy of remark, that in a small temple on the right bank of the Nile, a gallery passes round it in the thickness of the wall; a circumstance, which points out an origin or coincidence with sacred edifices of more modern times, in the western world.

Hermopolis.

Portico.

At HERMOPOLIS, there still exists a magnificent portico, consisting of 12 columns in two rows, each eight feet diameter, and standing at the distance of one diameter from each other, excepting in the middle, which is more. The length of this portico is 120 feet, and the height 60 feet. Each of the columns represents a bundle of the lotus tied together.

Difference in plans.

There appears to have been a considerable difference in the form of the ground plans of the Egyptian edifices. The entrance to Luxor is composed of two obelisks, which at present rise 70 feet above the surface of the ground, and are understood to be about 30 below it; two colossal statues of black granite, each 38 feet high; and two great moles or masses of building, of an oblong plan, and tapering sides, 55 feet high, and covered with hieroglyphics. And so closely are these large masses crowded together, that from the front of the moles to that of the obelisks, the distance is only 14 paces. The edifices at Karnac, Philee, and Hermopolis, have also large moles at their entrances, and the doorways are between their moles. To these succeed courts with peristyles, or covered passages, which lead to the grand porticos. In these instances, the number and magnitude of the parts appeared to have been chiefly had in view; but at Tentyra and Latopolis, there does not appear to have been any of these great objects at the entrance; it leads immediately into a beautiful portico, characterised by richness and perfection of workmanship. In some of these edifices, the sanctuary is placed at the extremity from the entrance; and, in others, it has courts and halls on each side of it. Whether these differences in arrangement arose from a gradual change of style, or whether each form was peculiar to the deity or purpose to which it was appropriated, it is now impossible to determine; but the perfection of the workmanship at Tentyra, Latopolis, and Apollinopolis, is incontrovertible evidence of an improved state of the arts.

In decoration.

Plate CXLIX.

Plate CL. Fig. 1, 3, 4, 5, 6.

Fig. 2.

In the outlines and decoration of their columns, the changes have also been very considerable. In the simplest, as those at the entrance of the tombs at Silsilis, (see Plate CXLIX.) they consist of representations of bundles of reeds bound together near the top with a cord, which is wound several times round them, having a square stone laid on their top, forming what is now known by the term abacus; and the part between this stone and the cord binding, apparently crushed down by the incumbent weight, so as to bulge out a little beyond the surface of the part which is firmly bound. The first change from this simple mode seems to have been to introduce mere bindings or belts in various parts of the shaft; and in the divisions between them, to represent alternately reeds and hieroglyphics. The bulged part near the top was also decorated by reeds and hieroglyphics, and sometimes by triangular flutings. Afterwards, this upper part was formed into elegant vase-shapes, decorated with the stalks, leaves, buds, and blossoms, of the lotus or lily of the Nile; and, occasionally, leaves of the palm, vine, papyrus, and date were introduced. (See Plate CL. Fig. 1, 3, 4, 5, 6.) At Tentyra, each capital is composed of four heads of the goddess Isis; and here the abacus, instead of being a plain square thin stone, projecting beyond the surface of the shaft, (as at Silsilis), is of a cubical form, only equal to the diameter of the column, and decorated with hieroglyphics, as was the whole surface of the shaft. (See Plate CL. Fig. 2.) At Tentyra, the shaft was continued, of equal diameter, quite down to the ground; but at Latopolis, and several other places, it was made narrower, just at the bottom, and was placed upon a square or rounded plinth. At the Memnonium, in place of columns, human figures are introduced, as they were afterwards by the Greeks, who pretended to have invented and named them Caryatides. (See Plate CXLIX. Fig. 2.)

Caryatides.
Plate CXLIX.
Fig. 2.

Outlines of edifices.

Entablature.

Sculpture.

In the general façades, the shapes remained nearly the same; the extremities of the space in which the front row of columns of the portico was placed, were terminated by perpendicular lines; but at the extremities of the façade, the lines at the external angles were always tapering. Upon each angle there was an astragal, or large bead, which returned horizontally along the top of the lintel or architrave; this architrave at Tentyra is three-fourths, and at Latopolis two-thirds of the diameter of the column. The general crowning member of the façade is always a very large cavetto, having a comparatively small projection, and decorated with vertical flutings or reeds; and, frequently, in this member, and sometimes on the architrave, over the entrance doorway, were sculptured the wing, globe, and serpent. The whole of the walls, externally and internally, were covered with hieroglyphics; and, it appears probable, that the general mass of building was first constructed, and the sculptures performed afterwards. The progress of the art of sculpture is very evident, from the different states in which it was found, being, 1st, A simple outline, cut very deep. 2d, Figures in very low relief, and of rude execution. 3d, Figures very bold and perfect, as at Tentyra; and, 4th, A sort of ornament, adopted by the Greeks and Romans, and known, in modern times, by the name of abarasque; but in no instance did any of those hieroglyphics or ornaments interfere with the outlines of the building, all of which have been carefully preserved; and this circumstance alone, tends, in no small degree, to produce that imposing effect so peculiar to Egyptian architecture.

Tombs.

Plate CXLIX.

It has already been observed, that amongst the ancient Egyptians, the sepulchre or tomb was considered their everlasting dwelling, and that the trouble and expence bestowed upon it, and upon preserving the bodies of their relations, occupied much of the time and attention of the living. Near principal cities are regularly found extensive ranges of tombs. In Upper Egypt, they were formed by excavations in the sides of the adjacent rocky mountains, (see Plate CXLIX.), into extensive galleries and halls, with smaller apartments for sarcophagi and mummies; and these, in many instances, were decorated with columns, sculptures and paintings, executed in the most masterly manner, and forming a striking contrast with the rudeness of the surrounding rocky desart. They were also disposed in successive gradations, evidently suited to the different ranks of society. But partaking more of the nature of sculpture than architecture, and also forming so extensive and interesting a subject of discussion, they require to be treated separately, which can be done with most propriety under the word Sepulchre, where not only the Egyptian, but those of other nations, will be fully explained and illustrated.

Memphis.
Pyramids.
Sphinx.

The total annihilation of Memphis, Heliopolis, and other structures, at the northern extremity of this wonderful valley, has left us only the pyramids, the enormous sphinx, with vestiges of a great causeway, and some tombs, as specimens of the power which reigned in the second capital; but these alone, after the expiration of 3000 years, are sufficient to excite astonishment. Some particulars relating to them have already been furnished in the historical Part; but as a full discussion, in all its bearings, does not fall under this article, we must, for that species of information, refer the reader to the word Pyramids.

Alexandria and Cairo.

Although Alexandria and Cairo have occupied distinguished places in the annals of Egypt, yet possessing little that is connected with its ancient architecture as a distinct school, and that little having been pillaged from the treasures of the Thebaid, it would be quite improper here to enter into any details respecting these splendid cities.

The works connected with the navigation of the Nile, their extensive canals and reservoirs, will be treated of under Inland Navigation and Ports.

General observations.

But previous to our dismissing the subject of Egyptian architecture, it may not be improper to introduce the following general observations. Although we have not any direct account of the manner in which the immense masses of stone which composed the antient edifices were raised from the quarries, carried to, and placed in their respective situations; yet it is evident, from the vestiges of the communications made from the Nile into the extensive quarries on its banks, as at Apollinopolis, Elephantina, Philee, and other places, that advantage had been taken of the annual rise of that river, to raise and float the great blocks which they employed. In all that regards the operations which afterwards took place, in removing them from the water to the building, preparing them for, and placing them in their several positions, such as raising obelisks and columns of great magnitude, and covering the latter with platforms which composed their terraces and roofs, we are left wholly to conjecture. In the course of such continued and extensive experience, it is natural to conclude, that whatever was the mode they had adopted, they had arrived at a great degree of perfection; but for the last two thousand years, the oppressed and enslaved natives have been as little qualified to explain in what manner the entrance to Luxor was constructed, as, at this day, the Greeks of Attica are respecting the buildings in the Acropolis of Athens. If descriptions, or intelligence of any kind, were ever committed to writing, they must have been destroyed by Cambyses, the Romans, or Amrou. What the Greeks drew from thence is very indistinctly acknowledged; for that vain people, as they had a just claim to much, endeavoured to arrogate original merit to themselves in all that regards architecture. Although the size and quality of the materials, and the principles of construction, are calculated to ensure durability, yet it must be confessed, that the climate is also equally favourable; for even Egyptian structures could not have withstood the effects of our frequent and severe changes of atmosphere during 3000 years.

Climate favourable.

Plutarch.

Plutarch, who travelled to Egypt with the view of investigating all that the priests taught respecting Osiris and Isis, describes their temples as having long wings, and extensive open avenues; and also as having secret and dark vestries, resembling the adyta of the Thebans. The result of the researches by modern scientific travellers amounts to nearly the same. Indeed, the local circumstances of the country and people, led unavoidably to the style which was adopted; there being no rain, it was chiefly on account of shade that the covering parts were required; their total ignorance of the principles of an artificial arch forced them to use large flat stones; their quarries afforded materials of any magnitude, and they had probably previously inhabited, or at least worshipped in caverns, first natural, and perhaps afterwards artificial; and these circumstances, with the applications of wealth and power in the hands of a numerous priesthood, with cloistered habits, and, for many succeeding ages, pursuing incessantly the same objects, seem to afford a sufficiently satisfactory explanation of the rise and progress of Egyptian architecture.

Modern travellers.

Shade wanted.

Montfaucon is of opinion, that Cambyses established the Mithratic worship in Egypt about 500 B. C. What seems to have chiefly suggested this idea, is the discovery of a curious representation of a sacrifice to the sun, in an artificial cavern near the ruins of Babain in Upper Egypt. It is hewn out of a rock in the middle of the mountain; it is about 50 feet wide, and as much in height, and between five and six feet in depth. The sun appears encompassed with rays, forming a circle 15 or 20 feet in diameter. Two priests, of a natural stature, their heads covered with long caps, terminating in points, stretch their hands towards the sun; the ends of their fingers touch the rays; two little boys, clothed like the priests, stand by their sides, and reach to them two great goblets; below the sun there are lambs killed, and extended on piles consisting each of ten pieces of wood; and below the piles are seven jars or diotas. On the other side of the sun there are two women and two girls, in full relief, joined to the rock by parts of their backs and feet only; behind and above these and the boys are several hieroglyphics. The tiara on the head of the priests very much resembles those of the Persians in a procession in the bas reliefs, found at Chilminac near Persepolis. The hawk and Ibis are purely Egyptian. This is a very curious monument, and is well deserving of attention. The whole is certainly very different from the other excavations in Upper Egypt.

Mithratic worship.

Singular cavern.

INDIAN ARCHITECTURE.

In regard to the practice of architecture in India, we must refer to the Historical Part for particulars respecting the cities of Oude, Canouge, Delhi, and Làhôre; and shall here only make an addition to the description of Agra.

India.

Cities.

It was built in the form of a crescent along the banks of the Jumna; its walls were constructed with stones of great size, hard, and of a reddish colour resembling jasper. It was four miles in extent, and consisted of three courts, with many stately porticos, galleries, and turrets, all richly painted and gilt, and some overlaid with plates of gold. The first court was built round with arches which afforded shade; the second was for the great Omrahs and ministers of state, who had here their apartments for transacting public business; and the third court, within which was the seraglio, consisted entirely of state apartments of the emperor, hung round with the richest silks of Persia. Behind these were the royal gardens. In front of the palace towards the river, a large area was left for the exercise of the royal elephants, and for battles of the wild beasts; and in a square which separated the palace from the city, a numerous army lay constantly encamped. Mandesto, who visited Agra in 1638, then in the zenith of its glory, says, it was surrounded by a wall of freestone and a broad ditch, with a draw-bridge at each of its gates. He states, that at the further end of the third court, under a piazza, were a row of silver pillars; that beyond this was the presence-chamber, with golden pillars; that within a balustrade was the royal throne of massy gold, almost incrusted with diamonds, pearls, and other precious stones; that above this throne was a gallery where the Mogul appeared every day at a certain hour, to hear and redress the complaints of his subjects; and that no person but the king's sons were admitted behind these golden pillars. He mentions also an apartment remarkable for its

Agra built in the form of a crescent.

Courts, porticos, galleries.

State apartments.

Pillars of silver and gold.

tower, which was covered with massy gold, and for the treasure it contained, having eight large vaults filled with gold, silver, and precious stones. Tavernier, who visited Agra near the end of the 17th century, and in the absence of the court had permission to examine the inside, describes a gallery, the ceiling of which was decorated with branched-work of gold and azure, and the walls hung with rich tapestry. The gallery which fronted the river, the monarch had proposed to cover over with a sort of lattice-work of emeralds and rubies, to represent grapes with their leaves, when they are green, and when they begin to grow red; but this design then remained imperfect, there being only three stocks of a vine in gold, with their leaves, enamelled with emeralds and rubies, representing grapes; being a specimen of what was intended for the whole.

Tavernier.

Lattice work, rubies, &c.

We have been thus minute in the description of the palace of Agra, because, having been built by one of the most enlightened princes of the East, it affords a perfect specimen of the scale upon which the monarchs of those extensive and rich countries acted. And it will be allowed, that the establishments of Akbar and his great rajahs, occupying four miles along the banks of the Jumna, and connected with a handsome and prosperous city, must have produced a picture sufficiently splendid, and emblematic of the wealth and power of the prince who erected it.

Cuttack palace.

Nine courts.

At CUTTEK, or Cuttack, the capital of Orissa, there is a fine palace. It consists of nine distinct buildings:—1. For elephants, camels, horses. 2. For artillery, military stores, and quarters for the guards. 3. For porters and watchmen. 4. For artificers. 5. For kitchens. 6. For the Rajah's public apartments. 7. For the transaction of private business. 8. Where the women reside. 9. The rajah's sleeping apartments.

The specimens here selected being the most noted, will, we trust, convey an idea of the nature of the Indian cities and palaces; and we shall therefore proceed to consider,

Temples.

Five different forms.

II. *Their sacred edifices.* We have already stated, that these were of five different sorts; that is, 1. Pyramids; 2. Excavations; 3. Square or oblong courts; 4. In the form of a cross; and, 5. Perfectly circular.

Pyramids.

1. We are here at a loss, equally as in the case of Egypt, to determine whether or not the construction of Indian pyramids preceded that of their excavations. To construct a pyramid of rude stones, is certainly a much simpler operation than forming a cavern ornamented with sculpture; so that although it may be conceived that mankind might, for the purposes of worship, make use of the simple plain cavern, either natural or artificial, previous to the construction of buildings of great magnitude on the surface, yet it is not very probable that the splendid excavations of Elephanta and Vellore, in which were rich sculptures, and even pyramids cut out of the solid rock, could have preceded a rude pyramid on the surface. But as the purposes to which the pyramids of Deogur and Tanjore are appropriated partake very much of the nature of the cavern, their entrance-doors being very small, their interior being lighted by means of lamps, and the middle chamber by one lamp only; there is some reason for supposing, that, in places where rocky eminences were not conveniently situated, or from motives now unknown, some change of ideas taking place, these pyramids might be constructed for purposes similar to the original cavern or grotto, in the same manner as the Egyptian pyramids are considered to have been done with regard to the tombs of the Thebaid. The external faces of the pyramids of Deogur and Tanjore are very rude, as will be shewn under the word PYRAMID, to which we must refer the reader.

Excavations.

2. In regard to excavations, they are numerous and extensive. In some instances, they are very simple and plain; in others, highly ornamented with architectural forms and sculptures. From Captain Wilson's paper in the 6th vol. of the *Asiatic Researches*, we learn, that an extensive branch of the Caucasus was named by the Greeks, Parapamis, from *Para Vami*, the pure and excellent city of Vami, commonly called Bamaiya. It is situated on the road between Balkh and Cabul, where vast numbers of apartments are cut out of the rocks, some of them so large as to be supposed temples. And Abul Fazel says, that in the Soubah of Cashmere, in the middle of the mountains, 12,000 apartments were cut in the solid rock. At this place there were 700 places where the figure of a serpent was sculptured. Although neither the precise form nor dimensions are given, yet from the great number of excavations, and the place being noticed by the Greeks, it must have, in former ages, been of importance at least for its sanctity; and its situation between India and Persia, renders it still an interesting subject of enquiry.

City of Vami.

The serpent.

In other parts of India, the excavated temples have fallen more frequently under the observation of well-informed scientific persons, who have, with laudable industry, furnished the public with exact representations, and full details respecting them. The three principal ones, and which our limits will only enable us to notice, are, Elephanta, Salsette, and Vellore or Ellora.

Elephanta.

ELEPHANTA is situated near Bombay, in an island so named from the figure of an elephant being cut upon the rocks on the south shore. The grand temple is 120 feet square, and supported by four rows of pillars; along the side of the cavern are from 40 to 50 colossal statues from 12 to 15 feet high of good symmetry, and, though not quite detached from the rock, boldly relieved; some have a helmet of pyramidal form, others a crown decorated with jewels and devices, and others have only bushy ringlets of flowing hair; many of them have four hands, some six, holding sceptres, shields, symbols of justice and religion, warlike weapons and trophies of peace; some inspire horror, others have aspects of benignity. The face of the great bust is 5 feet long, and the breadth across the shoulders 20 feet.

At the west end of this great pagoda is a dark recess 20 feet square, totally destitute of ornament; the altar is in the centre, and there are two gigantic statues at each of the four doors by which it is entered. Niebuhr represents these statues as naked, 13½ feet high, and the sculpture good; their heads are dressed like the other statues, and they have each rich collars round their necks, and jewels in their ears. Hunter states, that, on entering Elephanta, there is a feerandah or piazza, which extends from east to west 60 feet, that its breadth is 16 feet, and that the body of the cavern is on every side surrounded by similar feerandahs. (*Archæol.* vol. vii. p. 287.)

Canara or Salsette.

Canara, in the island of SALSETTE, which is situated also near to Bombay, is represented by Linschotten, who visited it in 1759, as being like a town. He describes the front as hewn out of the rock into four stories or galleries, in which there are 300 apartments; these apartments have generally an interior recess or sanctuary, and a small tank for ablution. In these recesses, as at

Dimensions.

Sculpture.

Elephanta, are representations of the Lingam deity. The grand pagoda is 40 feet high to the soffit of the arch or dome; it is 84 feet long, and 46 broad. The portico has fine columns decorated with bases and capitals: immediately before the entrance into the grand temple are two colossal statues 27 feet high, which have mitre caps and ear-rings. Thirty-five pillars of an octagonal form, about 5 feet diameter, support the arched roof of the temple; their bases and capitals are composed of elephants, horses, and tygers, carved with great exactness. Round the walls two rows of cavities are placed with great regularity for receiving lamps. At the further end is an altar of a convex shape, 27 feet high, and 20 in diameter; round this are also recesses for lamps, and directly over it is a large concave dome cut out of the rock. Immediately about this grand pagoda, there are said to be 90 figures of idols, and not less than 600 within the precincts of the excavations.

Mr Grose.

Mr Grose, who visited India in 1750, seems to be of opinion, that the labour required to construct Elephanta and Salsette, must have been equal to that of erecting the pyramids of Egypt; and though it is not mentioned which of the many pyramids he refers to, the remark sufficiently expresses his admiration of the greatness of these Indian works. He observes, (p. 92.) that the roof of Elephanta was flat; that of Salsette of an arch form, supported by rows of pillars of great thickness, arranged with much regularity; that the walls are crowded with figures of men and women, engaged in various actions in different attitudes; that along the cornice there are figures of elephants, horses, and lions, in bold relief; and above, as in a sky, Genii and Dewtah are seen floating in multitudes.

Ellora.

But magnificent as the excavations at Elephanta and Salsetta must appear, they are still surpassed by those near *Vellore*, *Ellore*, or *Ellora*, which is situated 18 miles from Aurungabad, capital of the province of Balagate, N. Lat. 19° 20′, E. Lon. 75° 30′.

Sir C. Mallet, in a paper he transmitted to the president of the Asiatic Society, and published in the sixth volume of their Researches, gives a detailed account of 16 of them.

Sixteen excavations.

1. Jugnath Subba.
2. Adnaut Subba.
3. Indur Subba.
4. Pursuram Subba.
5. Doomar Lyna.
6. Jun Wassa.
7. Comar Wana.
8. Chana, or oil shop.
9. Neelkunt Mah dew.
10. Ramish wur.
11. Kylas, or Paradise.
12. Dus Outar.
13. Tee Tal.
14. Bhurt Chutturghun.
15. Biskurma, or carpenter's hovel.
16. Dehr Wanar, or Hallulcore's quarters.

Plates CLI. CLII.

Of these we must, of course, confine ourselves to such parts as are calculated to convey generally an idea of their architecture; with this view, we have selected for engravings (See Plates CLI. and CLII.) the ground plan of Kylas, the entrance and section of Biskurma, the elegant entrance to the cave of Jugnath Subba, the temple of Indur Subba, and a singularly beautiful piece of sculpture at the door of Jun Wassa. We shall also give the description and dimensions of the Kylas and the Biskurma.

Kylas.

Kylas, alias Paradise, (aspect, west.) This wonderful place is approached more handsomely than any of the foregoing, and exhibits a very fine front in an area cut through the rock. On the right hand side of the entrance is a cistern of very fine water. On each side of the gateway there is a projection reaching to the first story, with much sculpture and handsome battlements, which, however, have suffered much from the corroding hand of time. The gateway is very spacious and fine, furnished with apartments on each side that are now usually added to the dewrics of the eastern palaces. Over the gate is a balcony, which seems intended for the Nobut Khanneh. On the outside of the upper story of the gateway are pillars that have much the appearance of a Grecian order. The passage through the gateway below is richly adorned with sculpture, in which appear Bouannee Ushtbooza on the right, and Gunnes on the left. From the gateway you enter a vast area cut down through the solid rock of the mountain, to make room for an immense temple of the complex pyramidal form, whose wonderful structure, variety, profusion, and minuteness of ornament, are too minute for description. This temple, which is excavated from the upper region of the rock, and appears like a grand building, is connected with the gateway by a bridge left out of the rock as the mass of the mountain was excavated. Beneath this bridge, at the end opposite the entrance, there is a figure of Bouannee sitting on a lotus, and two elephants with their trunks joined, as though fighting over her head. On each side of the passage under the bridge, is an elephant, marked (*a*) in the Plan, one of which has lost its head, the other its trunk, and both are much shortened of their height by earth. There are likewise ranges of apartments on each side behind the elephants, of which those on the left are much the finest, being handsomely decorated with figures. Advanced in the area, beyond the elephants, are two obelisks (*b*) of a square form, handsomely graduated to the commencement of the capitals, which seem to have been crowned with ornaments, but they are not extant, though, from the remains of the left hand one, I judge them to have been a single lion on each.

To preserve some order, and thereby render easier the description of this great and complex work, we shall, after mentioning that on each side of the gateway within there is an abundance of sculpture, all damaged by time, proceed to describe the parts of the centre structure; and then, returning to the right side, enumerate its parts; when, taking the left hand, we shall terminate the whole in a description of the end of the area opposite to the gateway, and behind the grand temple, exemplifying the whole by references to the annexed plan.

Centre below. Passing through the gateway (1) below, you enter the area (2), and proceeding under a small bridge, pass a solid square (3) mass, which supports the Bull Nundee stationed above: the sides of this recess are profusely sculptured with pillars and figures of various forms. Having passed it, you come to the passage under another small bridge, beneath which there is, on one side, a gigantic figure of the Rajah Bhoj, surrounded by a groupe of other figures, opposite to which is a gigantic figure of Guttordhuj, with his ten hands. At each end of this short passage commences the body of the grand temple (4), the excavation of which is in the upper story, that is here ascended by flights of steps on each side (5).

Right and left hand sides of the temple below. The right hand side is adorned with a very full and complex sculpture of the battle of Ram and Rouon, in which Hunomaun makes a very conspicuous figure. Proceeding from this field of battle, the heads of elephants, lions, and some imaginary animals, are projected as though supporting the temple, till you come to a projection (6), in the side of which, sunk in the rock, is a large groupe of figures, but much mutilated. This projection was connected with the apartments on the right hand side of the area by a bridge (7), which has given way, and the ruins of it now fill up the sides of the area. It is said to be upwards of 100 years since it fell.

Passing the projection of the main body of the temple, it lessens for a few paces, then again projects (8), and after a very small space on a line of the body of the temple, the length of this wonderful structure, if what is fabricated downwards out of a solid mass can be so called, terminates in a smaller degree of projection than the former. The whole length is supported, in the manner above mentioned, by figures of elephants, lions, &c. projecting from the bases, to give, it should seem, the whole vast mass the appearance of moveability by those mighty animals. The hindmost or eastern extremity of the temple, is composed of three distinct temples, elaborately adorned with sculpture, and supported, like the sides, by elephants, &c. many of which are mutilated. The left hand side (I mean from the entrance) differs so little from the right, that it is unnecessary to be particular in mentioning any thing, except that opposite the description of the battle of Ram and Rouon, is that of Keyso Pando, in which the warriors consist of footmen, and others mounted on elephants, and cars drawn by horses, though none were mounted on horses. The principal weapon seems the bow, though maces and straight swords are discoverable.

Centre above. The gateway consists of three centre rooms (9), and one on each side (9). From the centre rooms, crossing the bridge (10), you ascend by seven steps (11) into a square room (12), in which is the Bull Nundee. This room has two doors and two windows. Opposite the windows are the obelisks (*b*) before mentioned.

From the station of Nundee you cross over the second bridge (13), and ascend by three steps (14) into a handsome open portico (15), supported by two pillars (above each of which, on the outside, is the figure of a lion, that, though mutilated, has the remains of great beauty; and on the inside, two figures resembling sphynxes) towards the bridge, and two pilasters that join it to the body of the temple, the grand apartments of which (16) you enter from the portico by four handsome steps and a doorway, on each side of which are gigantic figures. Advancing a few paces into the temple, which is supported by two rows of pillars, besides the walls that are decorated with pilasters, there is an intermission of one pillar on each side, leading to the right and left to an open portico (17), projecting from the body of the temple; from the right hand one of which, the bridge already mentioned as broken connected the main temple with the side apartments, to which there is now no visible access, but by putting a ladder for the purpose; though I was told there is a hole in the mountain above that leads to it, which I had not time nor strength to explore. The access to the opposite is by stairs from below. The recess (18) of the Ling (19) of Mahdew, to which there is an ascent of five steps, forms the termination of this fine saloon, on each side of the door of which is a profusion of sculpture. The whole of the ceiling has been chunamed and painted, great part of which is in good preservation.

A door (20) on each side of this recess of the Ling of Mahdew leads to an open platform (21), having on each side of the grand centre pyramid that is raised over the recess of the Ling, two other recesses (22), one on each side, formed also pyramidically, but containing no image. Three other pyramidical recesses (23), having no images within them, terminate the platform, all of them elaborately ornamented with numerous figures of the Hindu mythology. Many of the outer as well as the inner parts of this grand temple are chunamed and painted. The people here attribute the smoky blackness of the painting within, to Aurengzebe, having caused the different apartments to be filled with straw and set on fire, which can be reconciled on no other ground than that he meant to efface obscenities, as there are many in the sculptures. Upon the whole, this temple has the appearance of a magnificent fabric, the pyramidal parts of which seem to be exactly in the same style as that of the modern Hindu temples.

Right-hand side of the area. This side of the rock has a continuance of excavations, as marked in the Plan; but all those below, except the veranda, which I shall quit for the present, are of little note; and those above, of three stories, called Lunka (24), which appear much more worthy of attention, are inaccessible, but by a ladder from the fall of the bridge. We shall therefore proceed to the

Left-hand side of the area. In this side there are excavations of some consideration below, from which you ascend to an upper story, called Par Lunka, by an indifferent staircase, into a fine temple (25); at the extremity of which is a recess, containing the Ling of Mahdew; and opposite thereto, near the entrance from the staircase, is the Bull Nundee, with two large fine figures, resting on maces on each side of the recess, in which he sits. The ceiling of this temple is I think lower than any of the foregoing. The whole of this temple is in fine preservation, strongly supported by very massy pillars, and richly ornamented with mythological figures, the sculpture of which is very fine. The ceiling, like the others, has the remains of painting visible, through the dusky appearance of smoke, with which it is obscured. Descending from Par Lunka, you pass through a considerable insculptured excavation (26) to a veranda (27), which seems allotted to the personages of the Hindu mythology, (a kind of pantheon,) in open compartments. These figures commence on the left hand with, 1. The Ling of Mahdew, surrounded by nine heads, and supported by Rouon. 2. Goura, Parwuttee, and beneath Rouon, writing. 3. Mahdew, Parwuttee, and beneath Nundee. 4. Ditto, ditto. 5. Vishnu. 6. Goura, Parwuttee. 7. A Bukta (votary) of Vishnu, with his legs chained. 8. Goura, Parwuttee. 9. Ditto. These representations of Goura and Parwuttee all differ from each other. 10. Ditto. 11. Vishnu and Luchmee. 12. Bal Budder, issuing from the Pind, or Ling of Mahdew. Here ends the left hand side, and commences the east extremity, or end of the area (28), in which the figures are continued, viz. 13. Goura and Parwuttee. 14. Behroo, with Govin Raj transfixed on his spear. 15. Dytaseer on a chariot, drawing a bow. 16. Goura and Parwuttee. 17. Kal Behroo. 18. Nursing Outar, issuing from the pillar. 19. Kal Behroo. 20. Bal Behroo. 21. Vishnoo. 22. Govin. 23. Brimha. 24. Luchmedass. 25. Mahmund. 26. Nunain. 27. Behroo. 28. Govin. 29. Bal Behroo. 30. Govin Raj and Luchmee. 31. Kissundass. Here ends the veranda of the eastern extremity; and we now proceed with that on the right hand (29), having in our description of that side stopped at the commencement of this extraordinary veranda, for the purpose of preserving the enumeration of the figures uninterrupted, viz. 32. Mahdew. 33. Ittuldass. 34. Dhurm Raj embracing Uggar Kaum. 35. Nursing destroying Hurn Kushb. 36. Vishnu sleeping on Seys Naug, the Kummul (Lotus) issuing from his navel, and Brimha sitting on the flower. 37. Goverdhun. 38. Mahdew Bullee, with six hands. 39. Krishna sitting on Gunoor. 40. Bharra Outar. 41. Krishna

Chitterbooz trampling on Callea Naug. 42. Ballaju. 34. Anna Pooma. It is to be observed, that almost all the principal figures are accompanied in their respective pannels by others explanatory of the character of that part of the history of the idol in which it is represented.

Dimensions of the Kylas.

	Ft.	In.
Outer area, broad,	138	0
Ditto, deep,	88	0
Greatest height of the rock, through which the outer area is cut,	47	0
Gateway, height,	14	0
Ditto, breadth, without the modern building,	14	4
Passage of the gateway, having on each side rooms, 15 feet by 9,	42	0
Inner area or court, length from gateway to the opposite scarp,	247	0
Ditto, breadth,	150	0
Greatest height of the rock, out of which the court is excavated,	100	0

Left side of the Court, lower story, viz.

A small cave, in front two pillars, and a pilaster at each end, with three female figures buried up to the knees with rubbish, length,	22	6
Ditto, breadth,	8	0
Ditto, height,	9	8
Another excavation, in front five pillars, two pilasters, length,	57	9
Ditto, breadth, within the benches that are round this cave,	6	0
Ditto, height, at the end of this is a staircase to the upper story,	10	4
Interval unexcavated,	20	0
Another excavation, having two large plain square pillars, and two pilasters in front, with a bench round the inside, the rock projecting beyond the pillars, length,	54	6
Ditto, breadth,	12	6
Ditto, height,	16	0
Doorway, leading to a gallery or veranda, 5 feet 11 inches high, by 2 feet 9 inches wide. Gallery containing figures. Length from doorway to the extreme depth of the whole excavation,	117	8
Ditto, breadth,	13	0
N. B. In this length are eleven pillars, each 2 feet 8½ inches square.		
Ditto, height within the pillars. The projecting rock is about three feet lower, extending irregularly in the course of the length, from 7 to 13 feet beyond the pillars,	14	8

End of the Area, opposite the Gateway, behind the Temple.

Whole breadth from side to side, measuring from the inner wall of the gallery on each side,	186	6
Breadth of the gallery, including the pillars, there being 17 in this range,	13	4

N. B. The rock projects beyond the pillars along this range, and the right hand one irregularly, from 15 to 22 feet, and is lower than the ceiling.

Right hand of the Court, lower story, viz.

Figure gallery, or veranda, of the same dimensions as the preceding parts of the same gallery, for the space of ten pillars, the angle one being included in the foregoing; three of which are broken, it is said, to make trial of the power of the deity of the place; and when it was found, that the superincumbent rock did not sink, the tempter, said to be Aurenzebe, forbore further trial.

	Ft.	In.
Doorway 2 feet 4 inches broad by 5 feet high, leads to a veranda; within this veranda is a room of 60 feet by 22, and 11 feet 4 inches high. Right end unfinished, length,	60	0
Ditto, breadth,	17	0
Ditto, height,	13	0
A small projecting room, 15 feet by 13, and 6 feet high, being choked with several finely sculptured figures. An excavation raised 12 feet from the surface of the court, length,	36	10
Ditto, depth,	14	9
Ditto, height,	12	0

There is a multiplicity of figures in this apartment, detached from the wall. Amongst the rest, a large skeleton figure, with a smaller one on each side. The principal is sitting, with each foot on a prostrate naked figure.

	Ft.	In.
An excavation, which has a small recess, opposite the entrance, of 6 feet by 7, and 8 high, length,	24	0
Ditto, breadth,	18	0
Ditto, height,	10	0
An excavation terminating the lower story, on the side, length,	24	0
Ditto, depth,	10	0
Ditto, height, except between the two pillars, where the roof is arched, (the first instance I have seen of the arch,) and is there 14 feet 8 inches high.	11	6

Left hand side, upper story, viz.

A small unfinished excavation, the dimensions of which were not worthy taking.		
Pur Lunka is a fine large excavation, ascended by a flight of 25 steps, and a doorway of 3 feet 8 inches broad, by 7 feet 7 inches high; length, exclusive of the recess, in which is the temple of Mahdew,	70	7
Ditto, breadth,	61	9
Ditto, height,	14	6
Recess, in which stands the temple of Mahdew, depth,	26	0
Ditto, breadth, (the temple on the outside is 26 by 20 feet,)	39	0

N. B. The whole of this apartment is full of figures, some very finely sculptured; and the centre floor is raised one foot, and the ceiling in proportion.

Right hand side, first story.

	Ft.	In.
A large room, formerly connected with the grand temple by a bridge, now broken down, length,	60	0
Ditto, depth,	18	0
Ditto, height,	16	0
Another room within the foregoing, entered by a door from it, having a bench all round. This inner room is very dark, having no light but from the doorway, length,	36	0
Ditto, depth,	29	0
Ditto, height,	11	0

Right hand side, second story.

Entered by a staircase from the right side of the foregoing, of 24 steps. A large room, of the same dimensions, as a correspondent one below, except two feet less in the height.

Another room within the foregoing,	depth	35	0
Ditto, ...	length	87	0
Ditto, ...	height	14	0

The rock seems to have given way in the centre of this room, and the rubbish has fallen in.

Centre.

Balcony over the gateway 14 feet by 8, and 8 high. A room within it, 9 feet square, and about 9 feet high. Another within it, same dimensions. One on each side from the centre, 22 × 15 each. Bridge 20 feet × 18, with a parapet, 3 feet 6 inches high. Ascent by 9 steps from the bridge into a distinct room, in which is the Bull Nundee, 16 feet 3 inches square. Another bridge, 21 feet × 23 broad, leading to the upper portico of the temple. This portico, with the parapet wall, is 18 feet × 15 feet 2 inches, and 17 high; within a bench that is rounded, of 4 feet high, by 3 feet 7 inches broad. You can enter this portico from the gateway, by a passage that the filling up of the rubbish has afforded; but the proper passage is by flights of steps on each side, *of 36 steps each*, leading up on each side the body of the temple.

Grand Temple.

	Ft.	In.
Door of the portico 12 feet high × 6 feet broad; length from the door of the portico entering the temple to the back wall of the temple, .	103	6
Length from the same place to the end of the raised platform behind the temple, ...	142	6
Greatest breadth of the inner part of the temple,	61	0
Height of the ceiling, ...	17	10

Two porches on each side, measured without, 34 feet 10 inches × 15 feet 4 inches.

The particulars of the intricate measurement of this fine temple will be best understood from the plan formed on the spot.

Height of the grand steeple or pyramid computed about 90 feet from the floor of the court, and of the smaller ones about 50; height of the obelisks about 38 feet; base 11 feet square, being 11 feet distant from each side of the room in which is the Bull Nundee. The shaft above the pedestal is 7 feet square. The two elephants on each side the court or entry are larger than life."

BISHURMA, OR VISWAKURMA KA JOOMPREE.

The Carpenter's Hovel. Front W. 5 S.

According to the legend, Bishurma * was the artist who fabricated the whole of these wonderful works in a night of six months; but the cock crowing before they were finished, they remained imperfect, and he retired, having wounded his finger, to this hovel, in which state, the figure in front (1) of the entrance of this beautiful excavation, is said to be a representation of him holding the wounded finger; but it is more probable, that the figure is in the act of devout meditation, as many fingers, with similar positions of the hands, occur. But quitting the fable for the fact, this excavation is, in beauty, inferior to none. In form it is unique, and in design elegant. The portico is light, and striking to the beholder. On the right hand, as you enter, is a fine cistern of water. Above the gateway (H,) which is richly sculptured on the outside, is a balcony, which seems well suited, if not intended, for a music gallery to the interior temple (I,) which has the appearance of an elegant chapel, with an arched roof, and is exactly in the style of a similar excavation at Canara on the island of Salsette, and another at Ekvera, near the top of Bhore Ghaut, first explored by Mr Wales the painter. At the upper end is the figure (1) above-mentioned. From the ceiling are projected stone ribs, following the curvature of the arch to the capitals of the pillars on each side, through the whole length of the excavation. Beside the grand aisle, or body of the excavation, there is a small passage formed by the row of pillars on each side round the altar; but it is dark and narrow. This singular form of a cave, wherever it has been met with, has conveyed the same impression of its being a place of congregation and adoration, rather than of residence or habitation, and has given rise to an idea, from the orbicular ceiling and the name and attitude of its inhabitant, that it may be meant to represent the Almighty, meditating the creation of the world, under the arch or canopy of unlimited space. It is necessary, however, to accompany this idea with an acknowledgment, that the similar caves of Ekvera and Canara are not inhabited by Bishurma,—they having only a very high altar, the top of which is circular, and situated as represented in the annexed drawing at the back of Bishurma.

Square inclosures.

Seringham seven inclosures.

3. The third kind of temples are those composed of square inclosures; the largest is that of Seringham, situated near Tritchinopoly. The pagoda is composed of seven square inclosures, one within another; each side of the outermost is a mile in length, making the whole four miles in circumference. The walls of each inclosure are 350 feet from those of the others; they are 25 feet high, and four feet thick. Each inclosure has four gateways, that is, one in the middle of each side, opposite the cardinal points. In the outward wall, the gateway which fronts the south is ornamented with pillars, several of the single stones 33 feet long, and five feet diameter; those of which the roof is composed are still larger. All the gateways are covered with figures emblematical of their divinities. In the innermost inclosures are the chapels. Into the last, which is 1024 feet square, and contains the sanctuary of Veeshnu, no European is willingly admitted; but during the wars

* Creator of the World, but allegorically artificer of Ram.

between the English and French, it was alternately occupied by each.

Chillambrum. The pagoda of Chillambrum, which consists of one square, only 1332 feet by 936, entered by a pyramid 122 feet high, has already been sufficiently described in the historical Part of this article.

Ahmed-Abad. The pagoda Ahmed-Abad in Guzerat, or pagoda of Santidus, consists of three courts surrounded with marble columns, and paved with marble. No person is admitted into the innermost court with their sandals on. All the porticos are covered with female figures of excellent workmanship; the inside of the roofs and walls are decorated with Mosaic and precious stones, (see *Tavernier* and *Thevenot's Travels.*) This pagoda was converted into a Turkish mosque by Aurenzebe.

Jumna-Mesgid. The Jumna-Mesgid is quadrangular, 140 paces by 120; round the inside of the inclosing wall runs a gallery, having its roof supported by 34 pillars. The temple itself stands upon 44 pillars, ranged in couples; the pavement is marble; in the middle of the front are three large gateways. On the sides are two gateways; each gate has a sort of pilasters: the minarets are Mahomedan.

Buswara. The pagoda of Baswara, or Bezoara, now a fort on the Vistnu river, is not inclosed by walls, but stands upon 52 lofty columns, with statues of Indian deities standing between them; it was placed in the midst of an oblong court, which was surrounded by a gallery, supported by 66 pillars. (See *Tavernier.*)

The cross. **Benares.** 4. The fourth kind are in the form of a cross. The most noted is that of Benares, in the city of Casi, on the banks of the Ganges, down to which there is a flight of steps. This, from the earliest period of history, has been devoted to Hindu religion and science. The form of the temple is that of a great cross, with a cupola in the centre, which, towards the top, takes a pyramidal form. At the extremity of each branch of the cross, which are of equal length, there is a tower with balconies, to which the access is on the outside. Within the temple, immediately under the central cupola, there is an altar, eight feet in length, and six in breadth, covered sometimes with tapestry, sometimes with cloth of gold and silver. Tavernier saw several idols, one, in particular, six feet high, having its neck decorated with a chain of precious stones; the head and neck only were visible; the body was covered with a robe. On the right of the altar was a golden figure, composed of an elephant, a horse and a mule; upon this the deity journeyed on his guardian care of mankind. In this pagoda was also an idol of black stone, or Sammena codom. Aurenzebe polluted this temple.

Mattra. Mattra, the Methora of Pliny, 18 miles from Agra, on the road to Delhi, is the birth-place of the beneficent god Chreeshna. The pagoda is constructed of the same stone as Delhi, and stands upon a very extensive octagonal platform of hewn stone. This platform is ascended by two flights of stone steps, which lead to the grand portal, composed of pillars with the usual sculptures. The pagoda is in the form of a cross, with a lofty cupola in the centre, and two others nearly similar on each side. The sanctuary is separated by a balustrade, behind which only priests are admitted. In the sanctuary is a square altar, 16 feet in height, covered with gold and silver brocade, and here stands the god Ram Ram; the head only is visible, and appears of black marble, with two large rubies for eyes; the body is covered with a robe of purple velvet.

Circular. Juggernaut. 5. Of those which are of a circular form, Sonnerat thinks that Juggernaut is the most ancient in India, and says that the Brahmins attribute it to the first king on the coast of Orissa, 4800 years. Its plan is a perfect circle, of immense size. Juggernaut is said to be only another name for the god Mahadeo, who is represented by the figure of a large bull, which projects out of the eastern side of the edifice: the image of Juggernaut stands in the centre of the building, upon an elevated altar, surrounded by an iron railing. Mr Hamilton describes the idol as being an irregular pyramidal black stone, and the temple deriving light only from 100 lamps. He compares the edifice to a great butt set on end. This place is the residence of the Arch-Brahmin of all India, and the sacred dominions are said to yield pasturage for 20,000 cows. See Buchanan's *Christian Researches.*

Temple of the Sun. Besides these, which are offered as specimens of the different forms of Hindu temples, there is one more which our general views of the matter require to be noticed. The Ayeen Akbery relates, that near to Juggernaut is the temple of the Sun, in constructing which, the whole revenue of the Orissa was, for 12 years, wholly expended; that the wall which surrounds the whole is 150 cubits high, and 19 cubits thick; that there are three entrances; at the eastern gate are two elephants, each with a man on his trunk; on the west are two figures of horsemen, completely armed; and over the northern gate, are two tygers sitting upon two dead elephants. In front of the gate is a pillar of black stone, of an octagonal form, 50 cubits high. After ascending nine flights of steps, there is an extensive inclosure, with a large cupola, constructed of stone, and decorated with sculptures of the sun and stars, surrounded by a border, composed of a variety of human figures, some kneeling, some prostrate with their faces on the earth, and some representing minstrels, also a number of imaginary animals. But of this splendid temple, so minutely described in the Ayeen Akbery, not a vestige is now to be found.

Sculptures.

Tanks for ablution. It may be observed, generally, that these temples, for the sake of ablution, are usually placed on the banks of the Ganges, Vistnu, or some sacred river; or where that is not the case, artificial tanks or reservoirs are constructed, generally of a quadrangular form, lined with freestone or marble, and having steps to descend into them. Crawford mentions several tanks from 300 to 400 feet in breadth. (Crawford's *Sketches*, vol. i. p. 106.) Some of these tanks cover 8 or 10 acres, have steps of masonry 50 or 60 feet long, are faced with brick-work, and plastered substantially and neatly. The corners of the tank are generally ornamented with round or octagonal pavilions. (*Oriental Sports*, vol. ii. p. 116.)

Birman empire. **Temples of Godama pyramidal.** In the Birman empire, which, for situation and various circumstances connected with its history, is one of the most interesting districts of the East, the temples of Godama are of a pyramidal form, of solid brick-work, placed upon an elevated terrace; and the base of the great pyramid is frequently encompassed by a double row of small ones, having its summit terminated by an umbrella made of iron bars into a sort of filigree work, and adorned with bells; many of these pyramids are from 300 to 500 feet high. In the larger temples, the umbrella, with at least the upper part, sometimes the whole, of the pyramid, is entirely gilded. Other temples, of similar shape, are hollow, and have images of Godama within them; but the images are more frequently placed in chapels, which encompass the pyramid. Dr Buchanan saw at Ava an image of one block of pure alabaster, of so large a size, that one of its fingers appeared about the length and thickness of a large man's thigh and leg. The whole statue must therefore have been above fifty feet high.

At one village, Colonel Symes saw 30 or 40 yards full

Numerous statuaries.

of statuaries, all employed in making images of the god Godama, and all in the same position, that is, sitting cross-legged upon a pedestal; the smallest exceeded the human stature. The price of this size was 100 tackals, or 12 or 13 pounds sterling. They work the marble with a chisel and mallet, and polish with three stones of different fineness; and, lastly, by rubbing with the hand, which gives a great degree of brightness and smoothness.

At Umapoora, were spires, turrets, and lofty obelisks. The fort is an exact square, with public granaries and storerooms, and a gilded temple at each angle, upwards of 100 feet high. In the centre of the front stands the royal palace, with a wide court in the front, beyond which is the council-hall, supported by eighty pillars, on eleven roods. The royal library is a brick building, raised on a terrace, and covered with a roof of a very compound structure; it consists of one square room, with an inclosed veranda or gallery round it. (See Colonel Syme's *Embassy to Ava*, 1795.)

With regard to the present practice of Hindu architecture, we learn, that in Benares, their holy city, situated on the north bank of the Ganges, 460 miles N. W. of Calcutta, the streets are so narrow as not to admit of two carriages to pass one another. The houses are built with large stones, accurately joined. Some of them are six stories high, with terraces on the summits; a band or string course, decorated with sculpture, tolerably well executed, serves to mark externally the division of each story. The windows are very small. The houses on the opposite side of the streets sometimes communicate by galleries. The number of houses built of stone and brick are reckoned at 12,000; those with mud walls 16,000. In this city there is a stupendous observatory, a great number of Hindu temples, and a spacious mosque, built by Aurenzebe, from the minarets of which, the whole city may be seen.

By the kindness of a gentleman, whose opportunities and disposition for accurate observation have qualified him to afford the most authentic information, we are enabled to give the following account of the modes pursued by the Hindoos in the construction of their dwelling-houses: "The houses of the opulent are substantially built of stone and brick, with lime mortar, generally terraced with small bricks, about four inches square, and one inch in thickness; the beams are laid about 12 feet apart, and the joints ten inches. The masons begin to form the terrace at one angle of the building, sitting upon a plank, which is supported on the brick-work as they proceed, until they finish at the angle opposite to that at which they commenced. They have no planks upon the beams or joists to support the work below; but as the middle of the terrace (generally about 18 feet wide) is from five to six inches higher than the sides, an arch is thereby formed and supported by the surrounding walls, which are 20 inches in thickness, and have a parapet placed upon them, both for ornament and adding to the security. Over this brick arch is laid a coat or layer of jelly or gravel, or broken bricks, about the size of a large pea, mixed with quicklime and jaggury water; this is beat down hard with small hand mallets. Over this first coat is laid a second, composed of rough lime mortar, which is scored across. The third and last coat is a fine chunam; and this, altogether, forms so strong and firm a body, that a whole terrace sometimes falls down entire and unbroken. Many houses are built with pointed roofs, covered with flat tyles, four inches square, and three-quarters of an inch in thickness; others have a slight coat of lime, with pantyles, which are seldom above seven inches by four; they are semicircular nearly. The houses of the middling class are usually built in a square, and covered with tyles, with a seat round the inside of the square, about three feet high, and three feet in width, protected by a viranda; it is here the inhabitants sit to receive their guests. There are no windows in the external walls, but to each house there is a small door, and frequently a window; the latter placed as high as the viranda will admit. In the open square there is generally a wall, with a water-course below the house for domestic purposes. The houses of the poor are miserable; a few bamboos stuck in the ground, in a circular form, are collected, bent, and tied at the top, so as to represent an egg with the end cut off. They are seldom ten feet diameter, with a hole about three feet high to creep in at; this is shut with a leaf, tied on a simple wicker frame. The towns are generally a long street, with others at right angles, but seldom built with much regularity; some are large, some small; some are thatched and others tyled. Those in the interior parts of the country are inferior to those near the sea-coast towns where Europeans are settled."

From the account of Colonel Syme's embassy to Ava, we learn, that in the Birman empire, in private houses, the use of brick and stone are prohibited, and they are therefore all constructed of wood. They are all raised from the ground by wooden posts or bamboos, according to the size of the building, and made tolerably convenient. The roofs are slightly covered, and at every door stands a long bamboo, with an iron hook at the end, to pull off the thatch, and another with an iron grating, to stifle the flame by pressure. Firemen constantly patrole the streets at night.

PERSIAN ARCHITECTURE.

General remarks.

The ancient architecture of this extensive, rich, and interesting country, must be considered chiefly as it regards their cities, palaces, and tombs; for, with the exception of the temple of Belus, and some other temples, their mythology did not admit of sacred edifices. They were in this respect the reverse of the Egyptians and Indians, who, as has just been seen, seem to have devoted much of their time and attention to constructing and decorating temples. The accounts of the ancient Persian cities and palaces which have reached us, being very general and indistinct, we can add but little to what has already been stated in the historical Part. It will therefore be by the means of Persepolis alone, that we shall be enabled to enter into any particular details, or produce engraved specimens of the ancient school of this country; fortunately, sufficient remains of this palace have been preserved to afford satisfactory information in regard to many of its leading features. Of the present style of architecture, in their principal cities, some specimens will also be produced.

Babylon and Nineveh.

Streets.

The ancient cities of Babylon and Nineveh seem to have been existing at one time, and are said to have been nearly of the same form and extent. All accounts agree that this extent was very great, and that they had many wide streets, crossing each other at right angles. But Babylon was repeatedly destroyed and restored. The descriptions of it were taken after it had been rebuilt upon an uncommonly magnificent scale, by Nebuchadnezzar; and the comparisons, having formerly been just, were afterwards transferred to the new city. But that great degree of regularity which is mentioned in the descriptions of Babylon, are not to be attributed to cities of slow and gradual growth; it is the result of conquest at an advanced state of society. The most incredible circumstances respecting these cities, are what relates to

Walls.

their walls. Those of Nineveh are said by Diodorus to have been 200 feet high, and of a breadth sufficient to admit three chariots abreast. Those of Babylon are said by Herodotus to have been 350 feet high, 80 feet thick, and 60 miles in circumference; Diodorus says, six chariots might pass abreast. Others remark, that they were 50 cubits high, after being in great part demolished in the reign of Darius Hystaspes;

Gates.

that there were 25 gates on each of the four sides, opposite the ends of as many streets; and that these streets were 150 feet in breadth.

Remarks.

It is conceivable, that walls of the height of the London monument might have, during the long existence of a rich empire, been raised to protect so great a city as Nineveh; but it requires a much greater stretch of thought to conceive them, as in the case of Babylon, to be raised to a height equal to that of the cross which terminates the dome and cupola of St Paul's cathedral in London. Yet when we recollect, that Nebuchadnezzar was intoxicated with conquest, in possession of unbounded power and riches, and ambitious of creating a metropolis for all Asia, upon a scale which should far surpass every city the world had seen, we shall hesitate in condemning as improbable even the descriptions of Herodotus.

Built of rick.

All these mighty works were built with bricks. It is probable that, being situated in rich plains, proper stones were not easily procured. The excavations from the protecting ditches on the outside of the walls, furnished clay for bricks, and they were laid in mortar of bitumen. They are the earliest specimen of cementitious building we know of, and was no doubt the result of working with bricks.

Persepolis.

Le Brun, after much elaborate discussion, concludes, that Persepolis was built by Darius and Xerxes; and Strabo says, that after the kings of Persia had ornamented the palace of Susa, they did the same to Persepolis and Parasgade. No traces of any city remains. The ruins are usually named the House of Darius, or Chilmenar, that is, the Forty Columns. (See Plate CLIII.)

PLATE LIII.

Travellers, probably misled by this, have said that there were only 40 columns: but Le Brun discovered the traces of 205. He found 19 standing in January 1705. He asserts that there is no appearance of any thing belonging to a temple; but that it certainly is the remains of the palace destroyed by Alexander.

The pa- ace.

He traced the façade 600 paces from north to south, and 300 from east to west.

Descrip- son.

The door-ways or entrances which remain, have a perfect resemblance to those which are between the great moles at the entrances into the Egyptian temples. (See Plates CLIII. and CLIV.)

PLATES LIII. and LIV.

They have tapering outlines; and the crowning member is a large cavetto, similarly fluted. The columns are of more slender proportions than the Egyptian, being about 13 diameters high; that is 72 feet high, and 17.7 diameter. Each has a moulded base, 4.3 high, and 24.5 in circumference. Their capitals occupy about one-fourth of the whole height of the column. The shaft does not diminish, and in this bears a resemblance to those at Tentyra. The capital at Tentyra, also, by having first four heads of Isis, with a sort of drapery, and above that an ornamented square member of considerable height, occupies a space much greater in proportion to the column, than the vase capitals. But the Persepolitan capital occupies a still greater proportion of the whole height.

emarks.

It is possible, as alleged by some historians, that these columns, and the numerous sculptures at Persepolis, have been executed after the time of Cambyses, by Egyptian workmen; or that the idea of constructing columns of this magnitude of stone, may have been suggested by those of the Thebaid. But the Persians, detesting the Egyptian mythology, and instead of temples, being engaged in constructing palaces, they adopted representations of the ornaments with which they had been accustomed to decorate the posts and walls of the public apartments at their splendid festivals. The Persepolitan capitals therefore convey the idea of rich silks and feathers having been tied round the upper part of tall wooden posts; and, as has just been shewn in the case of India, rich silks, feathers, and precious stones, have always been the materials with which eastern monarchs formed their most gorgeous decorations. By inspecting the Plate of Persian capitals it will be seen, that they exhibit distinct representations of the spirals of the volute, said to have been invented long after by the Ionian Greeks.

The appearance of the tall slender columns, and their not having been any fragments forming parts of a roof found amongst the ruins, has led some to conjecture, that Susa being the winter palace, Persepolis was a summer residence only, with a temporary covering. The roof may, perhaps, have been slightly constructed of wood; and the interior covering and decorations being silks, &c. may have been occasionally fixed up and removed as the court was present or absent; but economy never having been attributed to Persian princes, even this circumstance does not wear an air of great probability; and much less that roofs and partition-walls were alternately fixed up and removed. Respecting the nature of the partition-walls, and the forms and dimensions of the apartments, we are left quite in the dark.

Sculptures.

The sculptures upon the terraces and sides of the stairs are very numerous. Le Brun considers them triumphal processions; and from the circumstances connected with them, endeavours to determine the era of their execution. He observes, that the dress and arms are partly Persian and part Median. The Persians offered horses to the sun, and oxen to the moon, as shewn in the sculptures. In the processions there is the tiara worn by the nobles in the time of Cyrus, when it is known that the great lords did assist. The umbrella, which is so frequently represented, was in use amongst the Persians; the long robes with foldings are a Median dress. The offerings before the altar, as exhibited, were made by Cyrus, Cambyses, and other princes of the royal blood.

Tombs of kings.

Although the ancient tombs of the kings belong properly to the word SEPULCHRE, where the subject will be treated generally, yet in this instance, forming, as they do, one of the most striking features of Persian architecture, we cannot, amongst the scanty remains of that school, avoid describing, and also giving an engraved representation of the front or entrance to the principal one, where it is said the body of Darius was deposited. (See Plate CLIII.)

Descrip- tion.

PLATE CLIII.

To obtain a perpendicular front or entrance into the tomb, a recess is cut in the rock for about 60 paces in depth. The front so obtained is about 70 feet in breadth in the base, 40 in the decorated part, and about 70 feet in height. By consulting the Plate, it will be found to bear a striking resemblance to the entrance of the cave of Biskurma at Ellora. The lower columns which support the sculptured gallery have capitals composed of oxens heads and necks projecting from the top of the column. Upon the columns are represented four great beams as an architrave; upon this runs a cornice, which has 2 feet 9 inches projection; and upon this is a dado, where 18 lions are sculptured, nine looking from each side towards a small vase, which stands in the middle of the length. Above the lions are two ranges of human figures, fourteen in number, and nearly as large as life; they are each holding up both hands, as if to support the entablature. At each extremity of these there is a sort of column, crowned with the head of a strange animal. Above all these, upon three steps, is the figure of a king with something in his right hand, the form of which cannot be distinctly made out; but he holds a bow in his left hand. Before him is an altar, with a flame rising from it; and it is said that the figure of the sun was behind the king. Above the altar is a small figure, too indistinct to be made out. At right angles with the line of front, in the returning face of the rock, on both sides of the front area, there are niches with statues in them. Le Brun entered a tomb to the south of this; the entry had only two feet of height, and the vault was 46 feet broad and 20 deep. Two hundred and fifteen paces south of the edifice, there is a column now standing upon its base; and near it are the bases of eight others, at seven and eight paces distant from each other: the height of the base is 9 feet 6 inches. At the sides of the two bases towards the south, are two fragments of camels, which may have been upon the columns. Six hundred and fifty paces to the north, is another portico, not inferior to that which has been described. Le Brun found about 1300 figures of men and animals sculptured on the tombs; some of the men were from 7 feet 5 inches to 10 feet 7 inches high, some had parasols or umbrellas over them, and many were armed with lances, and combating lions.

Thirteen hundred figures.

Such are the splendid ruins of Persepolis. They bear incontrovertible evidence of antiquity; and although in some things they resemble Egyptian, and in others Indian edifices, they, especially in the palace, possess leading features sufficiently distinct to entitle them to be considered as a separate school. Yet as being, amongst numerous palaces, the only vestiges of lofty stone columns and numerous sculptures, and being traced immediately subsequent to the Egyptian expedition under Cambyses, they afford strong grounds for believing that Thebaid influence, by example, or workmen, or both, led to these works, so unlike what had formerly been practised in Persia. That the style was not spread over the empire, may be accounted for, from its immediate subjugation by the Greeks.

Modern practice.

With regard to the practice of Persian architecture in modern times, their sacred edifices have an uniform character of Turkish mosques; some in monastic quadrangles, with flat domes over each separate apartment, and others with lofty minarets, or tall pillars. The churches of the Arminian Christians are rectangular, with a circular recess on each side, and four great pillars in the middle of the cell. That of Echmiazin, the plan and elevation of which is given by Sir John Chardin, measures 102 feet by 88, exclusive of the circular recesses on each side; the pilasters at each of these recesses, and in the four piers occupying the middle of the cell, are said to be of stone, 72 feet in height.

"In architecture, as well as in sculpture," says Mr Kinneir, the most recent traveller in Persia, "the ancient Persians would appear to have surpassed their descendants. Of this we have many noble specimens in the ruins of Persepolis, Shuster, the hall of Kungaver, and the remains of the palace of Chosroes Parviz, at Ctesiphon. The chief ornaments of the modern buildings, are the domes and minarets; and considering the materials with which they are built, many of the colleges and mosques are large and magnificent structures. The grand mosque of Sultaun Khodabunda, in the plain of Sultanea, is particularly handsome, and many of the public edifices at Shirauz and Ispahan, are well worthy of attention.

The general outlines of all the cities in Persia are the same. They are surrounded by a mud, and sometimes by a brick wall, flanked at regular distances with round or square towers. The streets are narrow and dirty, having a gutter running through the centre, and the houses, which are low, flat roofed, and built of brick or mud, have each a small court, surrounded by a high wall. They have seldom or never any windows to the street; and that part of the sitting rooms which fronts the court is entirely open, with a large curtain to let down when the rooms are not in use. The palaces of the nobility, although mean in their exterior appearance, are both convenient and elegant within. They are divided into several courts, in the most retired of which is the haram, or apartments of the women. The centre court is usually square, divided into parterres of flowers, with a jet d'eau continually playing before the window of the *dewan kana*, or public hall. The walls and ceilings of this hall, are adorned with a profusion of paintings, and inlaid with looking glasses; the floor is covered with carpets and *numuds;* and one entire side of the room is taken up with large sash windows of painted glass. The apartments of the haram are frequently fitted up with great taste and magnificence, but the sleeping rooms allotted to strangers are, in general, small. The Bazars, or market places, in some cities, particularly those of Lar and Shirauz, may be accounted handsome buildings, but the mosques, minarets and colleges are the chief ornaments of the Persian cities." See Kinneir's *Geographical Memoir of Persia*, p. 52. Lond. 1813.

Inn.

"The royal inn, without the city of Cashan," says Sir John Chardin, "joining to the gate that looks toward the east, is the finest in all Persia. It is four-square, every front withinside being two hundred geometrical paces; and two stories, with an antichamber or hollowness below, that runs all along the length of the two fronts, raised about the height of a man above the court, and four inches below the level of the chamber. It is eight feet deep, paved with white marble, almost as transparent as porphyry. The stories on the sides contain fifteen chambers of the same figure; the two others had but ten, with a large one in the middle, having five chambers. The other apartments consisted of one chamber, fifteen feet long and ten broad, high and vaulted, with a chimney in the middle, and a square portico before, ten feet wide, covered with a half duomo, with a contrivance for a chimney on each side, which was for the servants to lodge in. The second story was contrived like that below, with a baluster four feet high, that let in the light, and ran round the structure. In the geometrical part of the draught, you may perceive a hexagonal in the midst of the entrance, every front of which is a large shop, where are to be sold all manner of belly-timber, wood, and forage. The entrance is under a high and magnificent portal, adorned with Mosaic work, like all the rest of the building; and upon the sides runs a portico, where you may lie in the day-time as conveniently and as pleasantly, as in the inn itself. The fountain in the middle of the court is raised above five feet; and the brims of it are four feet broad, for the convenience of those that will say their prayers after they have performed their purifications.

"The hinder part of the caravansary consists of very large stables, with places for servants and luggage, built almost according to the same symmetry as the apartments already mentioned, at least as to the form and bigness of storehouses, and lodgings for the poor, and the country people that bring their goods to sell; and the large gardens that lie behind this lovely palace of a caravansary, no less famous for its founder, Abas the Great, who caused this sumptuous structure to be erected. Near adjoining to it stands the Palace Royal; and over against it, another designed for the lodging of ambassadors. Both the one and the other, with very large gardens behind them, were built at the charges of that renowned monarch. Besides that, there is in the middle a void space for their carousals, and other exercises on horseback."—*Sir John Chardin*, p. 412, 413. London edit. 1686. See CARAVANSERA.

CHINESE ARCHITECTURE.

Chinese architecture.

General remarks.

Before leaving Asia, we must advert to the architecture of a people, singular in many respects, placed at the eastern extremity of the Old World, and far removed from the restless activity and ambition of Arabs and Europeans. The extensive and populous empire of China has long remained stationary, with regard to customs, arts, and sciences. The practice of its architecture has been too long established, and our intercourse with the country too recent, to enable us to trace any account of its origin; but the general principles of its construction have evidently been taken from the tent. Its cities are only large encampments. In each individual building, the outlines of its form, its numerous small parts, its slender columns and slight covering, are all measured and modelled by the tent.

During the last two centuries, China has, however, been frequently visited by men of talents and observation, who, in spite of the jealousy of its government, and the prejudices of its inhabitants, have acquired and communicated minute and satisfactory accounts of the practice of its architecture. The authors from whom we shall chiefly select information, are, Duhalde, Le Compte, Chambers, and Barrow.

Sir William Chambers.

From Sir William Chambers we learn, that there are temples of various dimensions and forms. 1. Some very small, consisting of one apartment only. 2. Having a court, surrounded by a gallery leading to a ting (or large apartment) containing idols. 3. Composed of several courts, encircled by galleries, wherein Bonzes have their cells, and the idols their halls; these last are more properly convents. 4. The lofty tower, or Taa.—All these are known by the name of Pagoda.

Pagoda of Ho-nang.

The first object in the pagoda of Ho-nang, in the south suburb of Conan, is an extensive court, where an avenue formed by three rows of trees conducts to a vestibule, which is open, and ascended by steps. This is succeeded by a second vestibule, containing four colossal statues, composed of a sort of stucco representing marble; they are seated, and have in their hands various symbols. This last vestibule leads to a large court, encompassed by colonnades and cells for the Bonzes, and having in the middle four pavilions or temples, two stories high, filled with idols, before which the Bonzes perform their religious rites. In the corners of the court are also four pavilions, where the superior Bonzes reside. Behind the colonnades, between the cells, are four halls which contain idols. Near the middle of the length of this large court, two smaller courts surrounded with buildings are projected, of which those on one side serve for kitchens and refectories, and those on the other for hospitals. The forms of the pavilions are various. The cells of the Bonzes are very small, and have no light except what is admitted by the door. The pavilions and their pillars, as well as those of the colonnades, are of wood, with marble bases. All the buildings are covered with tiles of coarse porcelain, painted green and varnished.

This disposition common.

This disposition is common to all temples of this sort; and by omitting the pavilions in the middle of the great court, it bears a near resemblance to most Chinese edifices of importance. The palaces of the emperor, princes of the blood, mandarins, and Kong-Quaen, or colleges of letters, are all nearly of the same form.

Lofty towers or Taas.

To the lofty *towers* the Chinese give the name of *taas*; but they are known to Europeans by the name of *pagodas*. Duhalde says, they are so common, as, in some provinces, to be met with in every city and large town, and even in the villages. The most celebrated are the Porcelaine Tower at Nang-king, and that at Tong-Tschang-Fou. Of the former, from Duhalde (Vol. I. p. 129,) we learn, that this tower, unquestionably the tallest and most elegant in China, has eight faces, each 15 feet in breadth, and is 20 Chinese toises (200 feet French) in height. It is divided into nine stories, by floorings within, and cornices without, which support small roofs covered with glazed tiles of a green colour. From p. 200 of the same volume, we learn also, that the tower at Tong-Tschang-Fou consists of eight stories; that its outside is of porcelain, decorated with various figures; that the interior is lined with highly polished marbles of different colours; that a staircase, formed in the thickness of the wall, leads to the several stories; and that at each story there is, on the outside, a marble gallery quite round the tower, protected by lattices of gilt iron. At each corner of these galleries small bells are suspended. These octagonal towers diminish as they ascend, as well in the height as in the breadth of each story; and, in general, the apex of the edifice supports a long pole, encompassed by a number of iron rings, and secured by eight chains fastened at one end to the top of the pole, and at the other end to the angles of the upper roof. In some of these towers, the stairs are in the inside in the middle of octagonal chambers, and the cornices consist of a fillet and large cavetto, decorated with representations of the scales of fishes, an ornament very common in China.

Porcelain tower of Nang-king.

Tong-Tschang-Fou.

Plate CLV.

In Plate CLV. is given an elevation of a Taa or pagoda of this sort, which is situated upon the shore of Ta-ho (great river,) between Canton and Hoang-Pour.

Imperial palace.

Respecting the *imperial palace*, Duhalde furnishes a description given by a missionary who was admitted into the presence of the emperor in his own apartments, of which the following is the substance: The southern gate never being opened but for the emperor, he entered by a western gate into a court which lay to the south of the palace. Its form was a double square; at each extremity was an edifice of an oblong form, two stories high; the lower story having three openings like the gates of a city, the court from north to south was more than 200 geometrical paces; it was paved with coarse bricks laid on edge, and intersected by walks paved with large flat stones. In passing from this to a second court, a canal lying east and west was crossed by one of six bridges of white marble, erected near its middle, and facing four vaulted gateways, which are surmounted by a large platform or turret, and upwards of 20 geometrical paces in breadth. At the entrance of the bridge leading to the middle gateway were two large round columns of white marble, placed on pedestals, inclosed by a balustrade of the same material, and having two lions, seven or eight feet high, standing upon plinths, and apparently all of one block. This second court is scarcely 100 geometrical paces in length, and about half this in breadth. At the entrance of the court are other two columns of white marble, decorated with dragons in relief, and two small wings placed a little below a flat and very large capital. From this there was a passage into a third court twice the length of the second, and a little wider, by five gateways similar to the former. The gates are very thick, and covered with iron plates, which are fastened by means of rows of copper nails, with heads larger than a man's fist. All these buildings are elevated on a soclé or plinth about the height of a man, built with pieces of reddish-grey marble badly polished. All the courts are surrounded by low buildings, covered with yellow tiles. At the termination of the third court was an edifice of moderate length, flanked with two pavilions, each two stories high, encompassed by galleries. These are connected by wings terminated by two pavilions similar to the former. The lower story of this edifice is raised on a platform of brick about 35 feet high, crowned with a parapet with small inclosures. The base of the platform, to within six feet of the lower story, is built with marble; its lowest part is pierced with vaulted apertures, shut by gates similar to those already described, only that the brass nails and fastenings are gilt. Having passed these three courts, a fourth, of about 80 geometrical paces square, is entered: this is encompassed by galleries occasionally intercepted by small open saloons, opposite to which are staircases with balustrades of white marble. This court is intersected by a small canal, lined with white marble, and having marble balusters along its edges: there are four or five bridges over this canal, each of a single arch of white marble, decorated with mouldings and bas reliefs. At the extremity of the court is a magnificent saloon, approached by three staircases similar to those already described. In a fifth court, of dimensions and shape similar to the last, is a square perron of three stories, and at each story encompassed by a white marble balustrade, the height is about 18 feet: It is built on a soclé or plinth of coarser marble, about six feet in height; the ascent is by three staircases, the middle one of which is the most considerable. Eight bronze vases, about seven feet high, adorn the summit of this perron. At its base, near the principal staircase, are two enormous figures of lions in bronze; this edifice stands opposite a magnificent hall. From hence passed through two other courts differing little from the last; and from thence through a door on the right into an eighth court, about 200 paces in length; at the end of this, a large open hall on the left; and from thence into a ninth court, rather smaller than the last; at the extremity of this, there was an edifice of an oblong form, of two stories high, like the former,—a sort of causeway raised six or seven feet, paved with marble, and protected by a balustrade of the same material, led to the edifice which contained the emperor's apartment.

Sir W. Chambers states, that the Chinese do not distinguish their places of worship by any particular form. Thus, the *Ting* or *Tong* enters into all sorts of buildings, in almost all temples, all palaces, over gates of cities, and in every place where a display of magnificence is intended. In temples, three sorts are met with, and a fourth in most gardens.

Ting of pagoda of Cochin-China.

The Ting of the pagoda of Cochin China is raised on a basement, and approached by three flights of steps; the plan is square, encompassed by 24 columns, which support a roof which has a balustrade to protect a gallery quite round the building. The upper story is of the same form and dimensions, having dragons at the angles of its roof; the breadth, including the columns, is equal to the height; the body of the building occupies two thirds of this space; the height of the order is two thirds of the breadth of the body; the height of the second story is two-thirds of the first; the columns are nine diameters high, the bases two diameters; the beams and consols, which occupy the place of a capital, are one diameter; the entrelas, or frieze, under the first roof, is also one diameter in height.

Second sort of Ting.

The second sort of Ting differs only from the former by its upper story having neither gallery nor balustrade, and in the covering of the colonnade, being brought close against the wall.

Third sort.

In the third sort, the lower story is also nearly the same as in the first; but in the upper story, on two sides, there are advanced columns which form galleries. In this Ting the lower columns are eight diameters high, the base one. All the columns, with the exception of those at the corners, have eight consols or brackets, which form a sort of capitáls; the columns of the second order have their diameters about $\frac{4}{5}$ of the lower, and are about $6\frac{1}{3}$ diameters high. They have no bases. Under the roof is an entrelas composed of squares and circles; the corners of the roof are ornamented with dragons and foliage, the top with two dolphins at the ends, and a flower like a tulip in the middle.

In some instances, the building is closed in front by moveable doors, and has five advanced columns; in other cases, the building is quite open in front, with four columns to support the roof. In two instances in the court of one of the pagodas at Canton, there are two pavilions covering two iron vases, used in the sacrifices of gilt paper to their idols on festival days; they are both octagonal, and have each eight columns supporting a roof, upon which there is a lantern and other ornaments. One of these pavilions is a little elevated, and surrounded by steps; the columns stand on bases whose profile differs little from that of the attic; a frieze, with inscriptions in large Chinese characters, goes round under the roof; the lantern, which is octagonal, has a top in the form of a semi-inverse, finished with a small globe surrounded by flowers. The other pavilion is raised on a soclé or plinth, and inclosed by an entrelas of artificial stone, made of a species of potter's clay, cast in wooden moulds. The pieces are fitted with so much ingenuity, that the joints can scarcely be discerned; the columns are without bases, and under the first roof is an ornament of interwoven lozenges. The lantern has eight small columns without bases or capitals, which support a conical covering, decorated with a dolphin over each column: The apex of the building consists of a pierced ball, with a flower upon it.

Fourth sort.

The fourth sort of Ting, found in gardens, consists of twelve columns. The one in the middle of a small lake at Canton, stands on a basement, and is encompassed by a balustrade; the bases of the twelve columns resemble the Tuscan; the covering which rests upon the columns is crowned with a lantern; the heads of the shafts of the columns are pierced with the beams which support the roof, and their extremities are decorated with small grotesque heads and bells; a frieze, ornamented with an entrelas, runs immediately under the roof. Another pavilion had ten columns, with a roof and lantern in form of a cone, and terminated by a ball. In Plate CLV. will be found elevations of two of these

Plate CLV.

tings or temples, which stand in the court of one of the pagodas in the west suburb of Canton.

Houses of the Chinese.

In *Chinese houses*, the distribution is precisely uniform. Those of the merchants at Canton are all near the side of the river; they are narrow and very long: in other respects, they differ not as to interior distributions from the general scheme; the ground-floor is traversed in its length by a wide passage, which extends from the street down the middle of the habitation to the river; the apartments are on either side, and consist each of a saloon for receiving visitors, and a small bed-chamber, to which is sometimes added a closet or study; in front of each apartment is a court, at the extremity of which there is generally a fish-pond or cistern, with an artificial rock in the middle, covered with bamboos and other aquatic plants; the sides of the courts are usually decorated with flower-pots, or with blossoming shrubs, vines, or bamboos formed into arbours. It is common to have a large porcelain vase on a pedestal in the centre, filled with the flowers called lien-hoa.

Decorations.

The great room or saloon is generally from 18 to 20 feet in length, and about 20 feet in width. The side which is next the court is open, and provided with a screen of canes, which is occasionally let down. The pavement is composed of squares of stone or marble of various colours. The walls are covered with mats to about four feet from the ground. The upper part is covered with white, or crimson, or gilt paper. Instead of pictures, as in Europe, the Chinese hang up large pieces of satin or paper in frames, and painted to imitate marble or bamboo, whereon are written, in characters of azure blue, moral distiches and proverbs, extracted from the works of Chinese philosophers. Besides these, some persons have certain large characters, traced by a masterly hand in Indian ink on glazed white paper. This ornament is in high estimation. The farther end of the saloon consists of folding-doors, the lower parts of which are latticed, and covered with painted gauze to admit light into the bed-chamber. The doors, which are of wood, are neatly executed, ornamented with a variety of characters and figures, and sometimes highly varnished, and painted red, blue, yellow, &c. The doors are left open during the night to admit fresh air. The chamber is very small, and is only furnished with the bed, and some varnished trunks for holding apparel. The beds are sometimes of greater magnificence. The bedsteads, which resemble those of Europe, are made of carved rosewood, or of lacquered work. At the side of the chamber is a passage leading to the closet, inclosed by walls, and lighted by a window. The walls are decorated like those of the saloon, with moral sentences, &c. The furniture consists of elbow chairs, sophas, tables, shelves, and books. On a table near the window are pencils for writing and drawing, and instruments used by the Chinese in calculations.

Besides these apartments, there is on the ground floor the dining-room, the kitchen, servants' room, bath, privy, and counting-house. Towards the street is the shop.

The leon, or upper story, consists of large halls, which occupy the whole breadth of the buildings. These are occasionally converted into chambers for visitors. This is accomplished by means of a number of pieces of framed wainscotting two or three feet in width, and ten or twelve feet long. With these, in the course of a few hours, the space is divided into as many small rooms as the circumstances require. Some of the partitioning pieces are cut down to within four feet of the floor, and the apertures filled up with very thin oyster shells, being sufficient to admit light into the apartments. Of this sort of shell all the windows of the Chinese houses are constructed.

One of the large halls, nearest the entrance, contains the image and altar of the household deity, placed so as to be seen by every person in entering. The remainder of the upper story is divided into apartments for the family; and over the shops into rooms for the shopkeepers. The façades next the street, are either quite plain or occupied by shops; there is no other opening but the door, and that is screened by a mat to prevent passengers looking in. From the river the façades, consisting of pillars and galleries, have an airy and pleasant appearance.

Building Materials.

Their building materials are chiefly bricks and wood; the former are either merely dried in the sun, or baked in an oven or kiln. The walls are usually about 18 inches thick. The bricks, which are about the size of those in England, are worked in the following manner: Three or four courses next the foundation, are laid quite solid through the breadth of the wall. Upon these, the next course is laid header and stretcher alternately in both faces of the wall. The headers being laid opposite each other, meet in the middle of the wall, and there is a void space left between them equal to the length of the stretchers, and nearly of the same breadth. The succeeding course is laid stretchers only through the whole breadth of the wall, by which the joints of the cross bricks or headers in the course beneath are covered with a whole brick. This mode saves time and expence. The tiles for covering the roofs are either flat or semi-cylindrical, the latter being laid upon the joints of the former. The Chinese always leave the timbers of the interior of the ceiling or roof exposed; they are sometimes made of costly wood, and sometimes inlaid with ivory, copper, or mother-of-pearl.

Columns.

The columns used to support the roofs are usually of wood, upon stone or marble bases. They are without capitals, the ends of the beams being morticed through the heads of the shafts. The height varies from 8 to 12 diameters; the diminution is gradual from the bottom to the top; the bottom of the shaft terminates with an ovolo; the bases have a diversity of profiles. 1. In the colonnade to the pagoda of Cochinchina, the columns are nine, and the bases one diameter in height. 2. In one of the temples of the same pagoda, the columns are nine, and the bases are two diameters in height. 3. In the colonnade of the great court of the pagoda of Honang, the height of the columns is nine diameters, and that of the bases one. The projecting ends of the beams at the top are decorated with monstrous heads terminating in foliage, and the consols which support them issue from the mouths of grotesque masks, carved in bas relief upon the columns. 4. In a small pagoda, in the eastern suburb of Canton, the columns are eight diameters and a half high, and the bases only three quarters of a diameter; the ends of the beams are carved, to represent dragons heads, and all the timber of the roof is ornamented with inlaid work of copper, ebony, ivory, and mother-of-pearl, representing monsters, foliage, &c. 5. The column most usually met with in Chinese houses, is from eight to twelve diameters, and sometimes more; and the base from one half to two-thirds of a diameter. The profile is like the Tuscan of Palladio. 6. In a small pagoda, in the street of the European factories, the columns are of stone, and of an octagonal figure. Their height is eight diameters, of a circumscribing circle, and they have no diminution. The bases in the profile resemble the attic. Their height is equal to twice the breadth of one of the sides of the column. This kind of column, with some trifling shades of variation, is to be met with in almost all the pagodas.

Le Compte.

City of Pekin.

We have hitherto proceeded upon the authorities of Duhalde and Chambers. We shall now give some particulars from Louis le Compte, given in his *Nouveaux Memoires*. His description of the imperial palace and pagodas, corresponds nearly with those already given. They are too general to afford any further satisfactory information. Respecting the city of Pekin, he states that the principal streets extend in a direct line one league between the gates, and that they are 120 feet in width: that each shop-keeper puts out, on a pedestal before his house, a plank, 20 or 25 feet in height, painted, highly varnished, and having a list of the articles he sells: that these, on each side of the streets, at equal distances, have the appearance of scenes in a theatre. Respecting the city gates, he represents them as consisting of two large separate square buildings, connected by two very thick walls, so that the space enclosed may contain about 500 men in battle order. The first building, which has the appearance of a fortress, has no direct passage through it; it is entered at the side wall, by a gate proportional to the rest. When turning to the right, a second tower is met with, which commands the city, and has a gateway like the former; but it is so long, as to become dark towards the middle. In approaching Pekin, these immense gateways have a striking effect. The arches are built with marble, and the rest with large bricks, laid in excellent mortar. The walls are so high, as to conceal the city. They are so thick, that centinels on horseback are placed upon them. At every bow-shot distance they are fortified with towers. The ditch is broad and deep, but dry.

Triumphal arches.

Of *triumphal arches*, which are very common in China, he states, that they consist of three arches, the middle one being the highest. The four columns which support them are sometimes round, but more frequently square. They have no bases, nor any capitals; but the shaft is fastened into the architrave. The frieze is very high in proportion to the rest; it is decorated with inscriptions, and beautiful figures; with knots wrought one loop within another, and with flowers and birds—all in very bold relief. Instead of cornices, they have before and behind, large flat marble stones, like pent-houses.

Mr Barrow.

Houses and mud-walls, all mean.

The foregoing accounts and description, though we have no reason to question their accuracy, are yet in so uniform a tone of admiration, as to render it evident, that the favourable features only are exhibited. In order, therefore, to chasten, and perhaps to render the picture more perfect, we shall present the reader with some descriptions from an equally accurate and more recent visitor, Mr Barrow. Sailing up the river Pei-hoo towards Pekin, he observes, "there are few trees, except near villages, which are of mean appearance; the houses generally consisting of mud-walls, one story high, and thatched with straw or rushes. Here and there a solitary cottage intervened. Nothing bore any resemblance to the residence of a gentleman, or that could be called a comfortable farm-house; and although villages were numerous, no assemblage of hovels were perceived, that properly could be classed under the name of a town, except that of Lee-koo, near the mouth of the river, and Ta-koo, a few miles higher, until we proceeded to the distance of about ninety miles, when we entered the suburbs of the large city of Tien-sing, stretching, like London on the Thames, for several miles along each side of the river Pie hoo; but neither the buildings nor the river would bear any comparison, even with those parts about Redriffe or Wapping. Every thing, in fact, that we had hitherto seen wore an air of poverty and meanness." See p. 70, 71.

City of Pekin.

Palace.

Again, "The great road to the capital lies across an open country, which appeared to be sandy and ill cultivated; and the few houses on each side were of mean appearance, being commonly built with mud or half burnt bricks, up to the very gates of Pekin. This city is surrounded by a brick wall, rather less than thirty feet high, but extending round a circumference of nearly fourteen English miles. The buildings within are all so low, as to be completely hidden by the wall. They are all constructed on the model of a tent, being supported by slight wooden pillars, and concealed by a dead brick wall to the street. Their roofs alone appear above this enclosure; and, being arranged in straight lines throughout the whole city, give it very much the appearance of a vast encampment. With the exception of four great streets, which lead to the gates, the rest of the city consists of very narrow lanes, and every part entirely without pavement, and filled with sand and dust. There are no aqueducts; and the well water is, for the most part, intolerably nauseous. There are no drains. There are very few buildings which rise above the level of ordinary dwellings, excepting the rice magazines, at the angles of the walls, and a conical temple or two." And again, "The very dwelling of the emperor, and the grand hall in which he gives audience, when divested of the gilding and gaudy colours with which they are daubed, are little superior, and much less solid, than the barns of a substantial English farmer. The principal hall of audience at Yuen-mi-yuen stood upon a platform of granite, raised about four feet above the level of the court. A row of large wooden columns, surrounding the building, supported the projecting roof; and a second row within the first, and corresponding with it. The interstices between the columns being filled with brick-work to the height of four feet, the space above this was a sort of lattice work, covered over with large sheets of oiled paper, and capable of being entirely thrown open on public occasions. The wooden columns had no capitals; and the only architrave was the horizontal beam that supported the rafters of the roof:" (See p. 124.) Again, "The grounds of Yuen-mi-yuen comprehends a circumference of ten English miles, well laid out, but far short of the description by Sir W. Chambers. The buildings are all slight, detached and irregular, and the greater part of those, included within the precincts of the palace, are mere hovels, or very mean cottages."

Stone and clay floors.

Furniture scanty and mean.

With regard to the accommodation of the first officers, he states, "the stone or clay floors are sometimes, indeed, covered with a carpet of English broad cloth, and the walls papered; but they have no glass in the windows; no stoves, fire-places, or fire-grates in the rooms; no sofa, bureaux, chandelier, looking-glasses, book-cases, prints, or paintings. They have neither curtains nor sheets to their beds. A bench of wood, or platform of brick-work, is raised in an alcove, on which are mats or stuffed mattresses, hard pillows or cushions, according to the season of the year. Instead of doors, they have usually screens made of fibres of bamboo. (See p. 194.) There is not in the whole empire a statue, a hewn pillar, or a column, that deserves to be mentioned."

Earl Macartney's embassy.

By the introduction to the account of Earl Macartney's embassy, we are informed, "that in Nan-king, in the province of Kiang-nan, though the streets are narrower than those of Pekin, yet they are well paved, and are bordered in some places with a variety of stones curiously inlaid. The gates of the city and the temples have a beautiful appearance; but the most striking edifice is the famous porcelain tower, which is an octagon building, nine stories, or 200 feet high, and 40 in diameter. A winding staircase leads to the top, from whence there is a noble prospect of the surrounding country. On each story is a room, adorned with paintings and other ornaments; but that which is the most beautiful part of this building is the cupola, which rises from the uppermost story, and is supported by a mast fixed in the floor of the eighth story, round which a large iron hoop winds in a spiral direction, giving to the whole the semblance of a hollow cone rising in the air, having on the top a massive golden ball. From each angular projection a bell is suspended by chains or wires, which produces a tinkling sound by every vibration of the wind. This magnificent structure takes its name from the variegated tiles with which it is covered. The Chinese pretend, that it hath stood 700 years, being erected by the Tartars to celebrate their conquest of this country; but others are of opinion, that it was built by the Emperor Yong-lo, and consequently that it is about 400 years old." Pages 9. and 10. of Introduction.

Temple of Fo.

" In the province of Fo-kien is a famous port called Hiamen, or Emouy. Here is a celebrated temple dedicated to Fo. It stands on a plain by the sea coast, and at the foot of a high mountain. The front of this building is 180 feet in length, and the gate is ornamented with figures in relief. Immediately within the entrance is a large portico, having an altar in the middle, on which is a gigantic figure of Fo, made of brass, gilt, sitting cross-legged. At the corners of this portico are four other statues in a sitting form, 18 feet high, each of which is formed of one entire stone. One of them holds a serpent, which is twisted in different folds round his body; another has a bow and quiver; the third has a battle-axe; and the fourth a musical instrument, resembling a guitar. Next to this portico is a square outer court, paved with stones of a grey colour, the least of which is 10 feet long, and 4 broad. There is a pavilion on each side of this court, with a dome at the top, which communicate with each other by a gallery. In one of these pavilions is a bell 10 feet in diameter; in the other is an enormous drum, with which the Bonzes proclaim the new and full moon. The Chinese bells are struck on the outside with wooden hammers. The two other pavilions are appropriated to the use of the Bonzes, who are obliged to entertain all travellers that come hither.

" In the middle of this court is a tower, round which winds a stone staircase, that leads to a temple, the dome of which is adorned with Mosaic work, and the walls with stone figures in relief, of animals and monsters. The roof is supported by pillars of varnished wood. The pavement is composed of shells so placed, as to represent birds, insects, flowers," &c.

" In this temple is an altar, on which incense is always burning, and the lamps are always lighted. At one end of the altar is an urn of brass, which emits a mournful sound on being struck; and opposite to it is a wooden machine of an oval form and hollow; and both are designed to accompany the voices of the Bonzes, in celebrating the praises of their idol. This deity is called Poussa, whose image stands on the altar, holding an infant in his arms; several inferior deities are ranged round him in respectful attitudes. On the wall are hieroglyphical characters in praise of the idol; and among others is a painting in fresco, representing a burning lake, in which several persons appear to be swimming, some borne by monsters, and others guarded by dragons and winged serpents. Out of the lake rises a rock, on which sits the god, holding a child, who seems to call to the men in the lake, who are prevented from ascending the rock by an old man, having hanging ears and horns on his head, and who keeps them off by a large club. The Bonzes are themselves ignorant of the meaning of this piece.

A god holding a child.

" Leaving the tower, we cross the court into a gallery, containing 24 statues of Chinese philosophers; and at the end is a dining hall for the Bonzes. After passing through a large apartment we enter the temple of Fo, which is decorated with vases, filled with artificial flowers; but the idol is veiled by a deep curtain of black gauze. On the declivity of the mountain are several gardens; and numerous pleasant grottos are cut out in the rock." Pp. 20, 21, and 22, of Introduction.

Inn near Pekin.

In the further account of the embassy, we are informed, " they stopped to breakfast at a village near Pekin. The inn in which they were refreshed was not like those in England. It had neither elegance or ornament; but the rooms, though small, were neat and cool. All kinds of refreshments were produced. The party were anxious to discover the capital; but no seats or villas announced its appearance. At last they came to one of the eastern suburbs. They passed through a paved street, full of manufacturers, shop-keepers, and purchasers.— The party were about a quarter of an hour passing through this suburb, when they came before the walls of Pekin. The ambassador's arrival was announced by the firing of guns; and refreshments were provided for the suite, at a resting place inside of the gate. The walls near it were paved with stone, but in other places with brick. Over the gate was a high watch-tower of several stories, each having sham port-holes painted on them. Outside of the gate was a semicircular wall, having a lateral gate, which, bearing a resemblance to the European plan of fortification, is probably a late addition. The walls of the city were about 40 feet high. The parapet was deeply crenated, but without regular embrazures, nor were any cannon seen on the walls; but in the mertons, there were loop-holes for archery. At the base, the walls were about 20 feet thick; and across the terepleine, on which stood the parapet, 12. The outside of the wall, though not quite perpendicular, was smooth, but the inside sloped considerably; the rows of bricks, of which it is built, being ranged like steps, one above and behind the other. Square towers flanked the outside of the walls, the distance between each being about 60 yards, and the projection of the curtain between them 40 or 50 feet. Many horsemen might ride abreast on the ramparts, the ascent to which is by slopes of earth withinside.

No seats or villas.

Walls of Pekin.

City of Pekin.

" On the entrance of this city, it appeared different from those of Europe, the streets of which are frequently so narrow, and the houses so high, that at one end of a street, the houses at the other seem to lean, and to bear towards those opposite. Here the houses were mostly of one story, and none above two, while the street itself was much above 100 feet in breadth. It exhibited also a gay and jovial appearance. As the street had no pavement, water was thrown upon it, to allay the dust. Across it stood a good building, called here Pailoo, which has been erroneously rendered a triumphal arch; it was built entirely of wood, and consisted of three gateways, the largest of which is in the middle; over these were three roofs, one above another, highly adorned. The design of this structure was expressed by large characters, painted and gilt on the uprights and transoms. They are erected to celebrate particular persons, or some important events.

"The first street ran in a regular line westerly, till it came to the eastern wall of the palace, which is termed the yellow wall, from the colour of the tiles with which the top is covered.

"Several public structures were thus covered. These roofs had no chimnies, and the sides and ridges were ornamented with various figures; the whole shining like gold, gave the appearance of grandeur in that part of houses where it was unusual. Near the gate were large stores of rice. Looking hence to the left, along the wall of the city, an elevated building was seen, said to be an observatory erected by the Emperor Yong-loo, to whom Pekin owes much of its improvements. The shops were highly decorated, and in a grand style. Some had on the top broad terraces, filled with flowers and shrubs. In the fronts were lanthorns of horn, muslin, silk, and paper, in frames of different figures. Goods were exposed to sale, as well on the outside of the shops as within." P. 311, 312, and 313.

"On arriving at the eastern side of the yellow wall, the embassy diverged to the right, and then the bustle decreased. There were no shops in this quarter; each house had in front a wall to screen the inner court from being seen, which is called the wall of respect. Near the middle of this side of the palace are treble gates, where the party halted. The space of ground was large. Some of the ground was raised into steep hills; and the spots from whence the earth was taken to form them were filled with water. In these lakes were small islands, decorated with fanciful buildings, and interspersed with trees. On the hills were the imperial palaces; and on the top of the highest were summer houses and cabinets, surrounded with tall trees.

"On looking to the north from this spot, at the end of a street running to the city wall, appeared the lofty structure, in which is an enormous bell, of a cylindrical shape, the sound of which, when struck on the outside with a wooden mallet, is heard in every part of the city. A little further to the westward of it was one of the northern gates, the watch tower on which was seen above the intervening houses. Beyond the palace gates to the westward, between the yellow wall and the northern part of the city, is a large lake, which, at this time, was nearly covered with the leaf of the Lien-wha." Pp. 314, 315.

"Many of the streets were narrow, having gates at the entrance, near which guards were posted to preserve peace. These gates are shut at night, and are not opened but upon emergency. The party crossed one street four miles long, from north to south, being interrupted only by several Pai-loos." P. 316.

Palace.

The palace at Pekin "was built in the usual manner of the houses of the great mandarins, and the whole was in the form of a long square, surrounded by a brick wall, the surface of which was a mere blank, except near one of the angles, where there was a gateway. This wall supported the top ridge of roofs; the lower edges of which, resting on an inner wall parallel to the first, composed a range of buildings divided into offices. In the other part of the inclosure were quadrangular courts of different sizes. In each of which were buildings, on platforms of granite, surrounded by a colonnade. The columns were of wood, about sixteen feet high, and about an equal number of inches at the base, lessening at the top about 1-6th. These had none of the properties of the Grecian architecture. At the lower ends, they were let into sockets cut in stones, forming a ring round each, somewhat resembling the Tuscan order. Between the columns, which were red, was wood-work, carved and ornamented, of a different colour. This colonnade supported the projecting part of the roof beyond the wall plate, of a curvilineal form, and turned up at the angles; thus every part of these buildings might be visited under cover. The number of pillars was at least 600. Next to the chief apartment allotted to the ambassador, was a high building, designed for a private theatre and concert-room, having all round a gallery for spectators, and retiring rooms behind.

"All the buildings were of one story, except that which was appropriated for the ladies. This was in the inner quadrangle. The front was a long and high wall, the windows of which were of Corea paper. Behind this hall was a gallery, at the height of near 10 feet, leading to several small apartments, lighted only from the hall. The windows within were of silk gauze, in wooden frames, either ornamented with needle work, or painted in water colours. This apartment, though smaller, was neater than most of the rest. A small black court, with offices, was attached to this part of the building. One of the outer quadrangles had a piece of water, in the middle of which was a stone room, in the shape of a covered barge. Others of the quadrangles were adorned with trees, and in the largest was a heap of rocks, firmly, but rudely piled on each other; and at one end was a small unfinished garden." P. 322-3.

"This city also contains the Tien-tan, or eminence of heaven. On this building is inscribed the character tien, or heaven. It is circular, to represent the concave of heaven, as the Tee-tan, or temple of the earth, is square, agreeable to the notions of the ancient Chinese." P. 327.

Another palace.

Palace between Hai-tien and Yuen-min-yuen. "It was settled that the chief articles should be placed on each side of the throne, in a hall of audience. This hall was very magnificent on the outside. Its approach was through three quadrangular courts, surrounded by separate buildings. It stood on a platform of granite, which was about four feet above the court in front. The roof was supported by a double row of wooden pillars, painted red and varnished, and the capitals decorated with different figures, highly coloured, especially with dragons, the feet of each having five claws. The figures of these monsters, exhibited on the houses and furniture of the princes of the court, have but four claws, the fifth being reserved for the emperor only. The entablature of the edifice is encompassed with a net of gilt wire, to keep off the birds from settling on any of the projections. The hall withinside is above 100 feet long, upwards of 40 broad, and above 20 in height. Opening pannels are placed between the inmost row of pillars on the south side." P. 317-8.

Farm house.

Farm house at Lowang. "In the way they were invited into a farm house by the tenant, who, with his son, regarded them with astonishment. The house was of wood, the uprights of which were of the natural form of the timber. The roof, which was without a ceiling, was covered with the straw of rice. The floor was of earth beat hard, and the rooms were divided by mats hanging from the beams. Two cotton spinning wheels were in the outermost; but the females had retired. Clusters of bamboo grew round the house, and also the sort of palm whose leaf resembles a fan, and is used as such." P. 173.

"The houses near the river (Pei-hoo) appeared as if they were built of mud, but on a nearer examination they

Houses built of brick baked in the sun.

were found to be of bricks baked in the sun, which, as well as the tiles on the roofs, were afterwards plastered with a substance like mud. There is no lime except from sea shells or stones, to be had at any great distance from the river, and a pebble is accounted a rarity." P. 217.

"The houses were mostly built of a lead coloured brick; those of the meanest habitations were of pale brown, and very few were red.

Different sorts of bricks.

"These different colours have probably arisen from the method of making the bricks. The brown had only been exposed to the solar heat; the blue to a wood fire in kilns, without being affected by the flames; while the red had sustained the force of the flame. On moulding the clay into its proper form, it is the eastern custom to lay the bricks in regular rows upon one another, having layers of straw between each range. Many houses here have two stories, contrary to the Chinese mode in general." P. 277-8.

Villages.

"The houses in most villages were enclosed with a fence made of the stems of the Kow-leang. Some of these villages are as large as European cities, but none are reckoned of note here, except such as are walled round.

Walls mostly of mud.

Roofs thatched with straw.

Court formed by wattles.

Habitations regulated by law.

Manner of building.

Larch fir.

Windows of paper.

Floors of marble or earth.

Galleries.

Distribution of apartments.

"During this slow progress, hardly half an hour passed without bringing a town or village to view. The walls of the houses in the last were mostly of mud, baked in the sun, or moulded between planks, and bound with them till it was hard enough to bear a roof; or of wicker work, coated with clay. The roofs were, in few instances, covered with green turf, but more generally with straw. The rooms were divided with lattice work, hung with broad paper, ornamented with images or moral sentences. Each house has a court round it, enclosed with wattles, or the stem of the kow-leang. Neatness and order characterised the whole. The walls that surrounded the towns were usually higher than the roofs of the houses within, and generally formed a square, facing the four cardinal points, with a gate in each. The streets were mostly narrow. The few large buildings were either for public uses, or the dwellings of men in office. The habitations, as well as the dress of the great, are regulated by particular laws, and with an especial regard to the convenience of the poor. The houses were generally plain, and of one story, the foundations being of freestone or granite, brought from the adjacent mountains. The walls were mostly of brick, and the roofs covered with rows of tiles, alternately concave and convex, cemented by clay. The larch fir is chiefly used in building. The windows are small, and made of paper. So little is iron used, that hardly a nail is to be seen in any houses. The floors are of marble or indurated earth. In more elegant buildings, a range of pillars, made of the trunks of firs, ran parallel to the outer walls, and formed a gallery. Thus the body of the roof rests on the walls, and the projecting part on the pillars. In some structures are double or treble roofs, a few feet above each other. The chief doors and windows of public buildings look to the south. These are, chiefly, a hall of audience for the administration of justice, college for students, temples, granaries to hold supplies against scarcity, and a public library. Common houses have no columns, but the shops have two poles crossed with boards, on which are inscriptions and representations of what are sold within.

"The furniture is simple, and the ornaments are few. Whatever is made of wood is painted red and varnished. These towns all exhibited the bustle of commerce. Trading vessels were constantly passing on the river." P. 390, 391.

Plate CLVI.

Plate CLV.

In Plate CLVI. we have given a view of the viceroy's palace at Canton, which Patrick Begbie, Esq. of Castlehill, has been so obliging as to permit us to copy, from a drawing he had made by a Chinese upon the spot. This, though very deficient in the perspective, appears to have been performed with the minute attention peculiar to that people. The architecture is in a meaner style than that of the pagodas shewn in Plate CLV.; but Europeans not being admitted into these places, this view is valuable, as exhibiting the disposition of their paltry sheds and ridiculous decorations; and likewise of the dress and positions assumed during some of their processions.

General remarks.

The impressions from these descriptions are certainly very different; but, from the whole, we may conclude, that a time has been when the whole of China was modelled by a people previously accustomed to live in tents; and that if any other mode ever did prevail, it has been completely annihilated. The Chinese cities have not, as in most other countries, that irregularity which is the result of rising from small beginnings, and under varying circumstances; on the contrary, they have precisely the same formality of character as if their plans had been previously arranged, and carried into effect under the controul of despotism; the tent having been rendered a fixed habitation, the patriarchal government directing every operation by fixed rules, and never permitting their notions to be disturbed by foreign intercourse. Chinese skill has been limited to dexterity and neatness in the whimsical decoration of the trifling members of tent architecture; instead, therefore, of rousing genius by public estimation and rewards, it has been repressed by custom and arbitrary enactments. The utmost of their exertions in architecture appears in their city gateways, which having no prototype in tent encampments, were, in some measure, left for genius to invent; but the system of precedent was too powerfully rooted to suffer even this to proceed beyond the demands of absolute necessity, and a system of gateways was also established. The same unpropitious regulations pervades all ranks, from the mandarin to the peasant; the former barely enjoying a precarious comfort, and the latter too generally existing in wretchedness, justify, we suspect too frequently, Mr Barrow's remarks. With the feelings which such reflections must unavoidably excite, he has possibly been led to notice and describe, rather unfavourable traits of the Chinese; but if we refer to the evidently partial descriptions of Duhalde, Le Compte, and Chambers, they present only gaudy, superficial, and trifling operations, adapted to the early stages of civilization, or the childish years of more advanced society. Although this style is totally unfit for producing impressions of dignity, sublimity, or strength, yet some of its features are admirably calculated for scenes of gaiety and festivity. Nothing can be more airy and elegant than a slender colonnaded building, raised upon a properly constructed basement, surrounded by slight curved roofs of varnished tyles, light latticed galleries, and crowned with a small open cupola, with a pierced globe and flower at the top; it seems scarcely attached to the earth; and, in country habitations, for the middle ranks of society, instead of aping the gigantic members of Greek and Roman temples, the Chinese mode of arrangement in two stories only, with their simple and unassuming members, seem deserving of attention. This climate will not admit of the precise forms or distribution being adopted, but the ingenious architect will be at no loss to preserve the character, and at the same time construct an appropriate edifice.

Greek, Roman, and Modern Architecture.

Greek. Having, we presume, made the attentive reader sufficiently acquainted with Egyptian, Indian, Persian, and Chinese architecture, we shall proceed to define another mode, more generally known and practised by Europeans: this, strictly speaking, ought to be denominated Greek architecture; but although all the principal features and modes of application are Greek, yet as the Romans also practised this school of the art very extensively, and likewise introduced new features and modes of application, they have deservedly acquired a share in the title.

General remarks. In treating this part of the subject fully and explicitly, we find that, on account of the modes practised by the ancients, having, with some slight shades of difference, been also adopted by the moderns, it is impracticable to keep them perfectly distinct; but we shall endeavour, in every section, first to point out the ancient practice, and add what has been introduced by the moderns in the course of the progress of the arts and sciences, and the total change of habits in society.

Of Materials.

It is chiefly from the valuable work of Vitruvius, that we are furnished with information respecting the nature of the materials used by the Greeks and Romans, and of the particular modes in which they were disposed in their buildings. From the accounts published by modern travellers and scientific artists, we are also furnished with further information respecting the practice of these people.

Materials. The materials chiefly made use of by them were *timber, marble, stone, bricks, lime,* and *metals.*

Timber. With regard to *timber,* the proper time for felling was reckoned from the beginning of autumn to the latter end of February, when the moon was in the wane. They considered wood when quite green, or too much dried, as equally unfit for working. For joists, doors, windows, they required that it should have been cut three years, and kept for a considerable time covered with cow-dung.

Marbles. The Greeks most usually made use of white marbles, as Pentilic, Parian, and that of Chios. The latter was very transparent.

The Romans employed many sorts, of various colours, and procured from many different countries, which were subjected to them in Asia, Africa, and Europe.

The ancients frequently included under the term marble, all hard stones which would receive a smooth fine polish; the moderns confine the name marble to such calcareous stones as are capable of receiving a fine polish.

Alabaster. This substance resembled marble in taking a smooth fine polish, but it is much softer and more easily worked. Gypseous alabaster, when polished, is slippery to the touch; it frequently contained as much carbonate of lime as to cause it to effervesce with acids; it was procured from Upper Egypt between the Nile and Red Sea, also from Syria and Carmania. The calcareous alabaster is white, yellow, red, and bluish grey; the fracture is striated or fibrous, in hardness inferior to marble; it is known under the denomination of common and oriental; Italy and Spain produce the best.

Stone. The stone which was employed appears to have differed very materially in its qualities; some becoming considerably harder in being exposed to the air, was worked immediately on being taken out of the quarry; but there was some of a softer kind, which, previous to being used, required to have its quality proved by two years exposure to the effects of the atmosphere.

Tiles. Of *tiles,* they had, 1. The unburnt kind, which were dried five years in the sun; and, 2. Those baked by fire, after having been made two years, they preferred a white chalky earth dug in the autumn, exposed during the winter, and made into bricks in the spring. The Greeks proportioned the size of the bricks to the nature of the edifice: the largest for public buildings, were five spans each way; those of the middle class were four spans; and the smallest, called by Vitruvius, *Diodori,* or by Pliny, *Lydii,* were two spans long and a foot broad; these last were for private houses.

It appears that those dried in the sun were mixed with chopped straw. Dr Pocock describes one of the pyramids constructed of brick: he measured some 13½ inches long, 6¼ inches broad, and 4 inches thick; also others, which were 15 inches long, 7 inches broad, and 4¾ inches thick. At Rome they were found by De Quincey of three different sizes; the least were 7½ inches square, and 1½ inch thick; the middle-sized were 16½ inches square, and 18 to 20 lines in thickness; and the largest were 22 inches square, and 21 to 22 lines in thickness.

Sand. Three kinds of *sand* are mentioned, that is, pit, river, and sea sand; of these, pit sand was reckoned the best; the white was preferred to the black or red-coloured, and the carbuncle to all; of the river sand, that was considered best which was found near torrents; the least value was put upon sea sand, and it was required to be well washed, to dissolve the saline matter before used in plastering or rough casting walls.

Lime. *Lime* for plastering walls was made from shells, river-pebbles, or a sort of pumice stone; the best sort of lime was accounted that made from white stone, which was dense and hard, and lost one-third of its weight in burning in a kiln, where it was kept about sixty hours. Their mortar was composed of one part lime and three of pit or two of river sand.

Metals. *Metals* were used, 1. Iron for chains, hinges, handles, and nails. 2. Lead for roofs, pipes. 3. Copper and brass were still more used for many of these purposes, or, 4. *Copper, brass,* and *lead,* mixed into a bronze for statues, bases, and capitals of columns, and in doors.

Moderns. Amongst the moderns, change of climate, natural productions, and the habits of mankind, have from time to time led to considerable changes in the kinds of materials used for the various purposes of architecture, also in the modes of preparation, and application of them.

Timber. General remarks. With regard to *timber.* Oak, for the greatest strength and durability, should be chosen from those soils where it has taken the longest time in arriving at maturity, and of two pieces equally dry, that should be chosen which has the greatest specific gravity, and that which will have its specific gravity least changed by being soaked in water: this observation will indeed apply to timber in general. A decay of the top is almost a certain indication of a decay of the tree; and a decayed branch or rotten stump bespeaks a defect in that part of the tree where it is situated. In a similar soil, trees which grow near the outside of a forest will be more durable than those near the middle of it; and in the same tree, the side which grew towards the north will be stronger than the south side.

When perfection of strength and texture is alone consulted, all sorts of timber are cut down in the winter, being at that time freest of sap, and most readily seasoned, and rendered fit for the purposes of building; but on account of the bark of the oak being of great use in tanning leather, that wood is always, in England, cut in the spring, or rather from April to June, according to the state of the season, and soon after the sap begins to ascend and the leaf to appear; if it is cut before the sap rises, the bark adheres to the wood, and cannot be stripped off, and if left until the leaf is quite expanded, the bark is less valuable; when the tree is felled and suffered to lie in the trunk, it will shrink in size, but this is probably from its discharging water, because, if a dry tree be laid in a damp place, it will increase both in weight and size. The part called the sap varies in quantity in different trees; it is least in bad soils, where the growth is slow; it is of very little use.

Oak. Oak, used in damp situations, appears to decay gradually from the external surface to the centre of the tree; the outside ring or addition it received in the last year of its growth decaying first, and afterwards that next within it, and then the following one. This appears to proceed from two causes; first, from the outward ring being, where whole trees are used, first exposed to the action of the atmosphere, which cannot reach the second until the first is destroyed; secondly, from the centre part of the tree having arrived at a greater degree of maturity than the outward rings, which are many years younger. But this must be understood only of trees which are not past their prime before they are cut down; for when a tree begins to decay from age, that part of the tree which is oldest, namely the central part, decays first; to this succeeds the parts which are next oldest, being the ring next the centre, and the other annual rings in succession gradually approaching the bark. A judicious builder will therefore, in the choice of his timber, always carefully examine the central part of the tree, especially of that which is next the root, and more particularly if the tree is large, and has the appearance of great age.

Seasoning. The best mode of seasoning oak is to put it in water. This, if in the log, should be done for a whole year or more, but, if cut in planks, less time is necessary; in either case, alternate soaking and drying is to be preferred. This, in planks, is very practicable; but, in regard to logs, one soaking and drying gradually in the shade, is, on account of the great labour attending the operation, most generally practised. After the planks have been soaked in water, they are dried by placing a strong pole in a horizontal position, at such a height as will admit of one end of each plank being placed on the ground, and the other resting against the pole edgewise, placing a plank first on one side of the pole, and then another on the other side alternately, thus leaving a space for the air to pass freely and dry them, and being exposed edgewise to the sun, they are not liable to split.

Ash. In ash, there is little difference in the quality through the whole thickness of the tree, the outside is rather the toughest: it soon rots when exposed to the weather, but will last long when protected.

Elm. Of elm, some sort will decay sooner than the brown or red. It is improper for roofs or floors, being generally cross-grained, and very liable to warp; it also shrinks very considerably, not only in breadth, but lengthwise. It answers well when used under water; it is not liable to split, and bears the driving of bolts and nails better than any other timber.

Beech. *Beech* is hard and close. There is a black or brown, and a white kind: the brown is tough, and sometimes used as a substitute for ash; it is improper for beams, because a small degree of dampness in the walls very soon rots the ends; it is fittest for furniture, or where constantly under water.

Poplar. *Poplar* is of a very close quality, is liable to the same objections as the beech in beams, but is well adapted for floors and stairs, being not readily inflamed: it rots soon when exposed to the weather.

Asp. *Asp* resembles the poplar in appearance; it is soft and tough; it lasts when exposed to the weather; it is equally good through the body of the tree.

Sycamore. The *Sycamore* and *Lime* are subject to the same objections, in roofing and flooring timbers, as the poplar and beech. The lime is something like the ash, and, like it, is greasy when worked smooth: It is suitable for furniture.

Birch. *Birch* is equal in quality quite across the body of the tree; it is very tough, but does not last when exposed to the weather; it is also subject to be destroyed by the worms.

Chesnut. *Chesnut*, viz. the sweet, or Spanish, (not the horse-chesnut,) is frequently found in old buildings in England; and although difficult to be distinguished from oak, differs from it in this, that wherever a nail or bolt has been driven into oak before it was dry, a black substance appears round the iron, which is not the case in chesnut.

Walnut. The *Walnut-tree* is, in Britain, now too valuable to be used in the framings of roofs or floors, and in furniture it has long been superseded by mahogany; it is now used chiefly in stocks of firelocks, fowling-pieces, pistols, &c.

Mahogany. *Mahogany* is used chiefly in furniture, but also sometimes in doors and window sashes; it is sawn out and seasoned by perching out in the winter, and drying in the open air, the use of fire is not advisable. This beautiful timber was introduced into England about the beginning of the last century: its first application was in a box for holding candles, made by a Mr Wollaston for a Dr Gibbons, who had afterwards a bureau of it; the Duchess of Buckingham had the second bureau. It very soon came into general use. It is divided chiefly into Jamaica and Honduras; the former is by much the hardest and most beautiful: they may be readily distinguished before they are oiled; the pores of the Honduras appear quite dark, those of the Jamaica as if filled with chalk.

Fir. *Fir*, being cheaper, and more easily wrought than oak, and next to it in usefulness, is more used in Britain than any other kind of timber. That most generally employed in carpentry is distinguished by the name of Memel, (which includes Dantzic and Riga); Norway, (which also includes Swedish,) is much used for the smaller timbers, and answers well either when exposed to the air, or under ground. Dranton, or Dram, is suitable for flooring. All these are very durable. American fir is much softer, but suits inside joinery work, such as pannels and mouldings. What is termed in England *white deal*, and in Scotland *pine wood*, that is, fir deprived of its resinous part, being very durable when kept dry, is much used by cabinet-makers; but, as it will not stand the weather, it is little used in carpentry or joinery.

Evelyn makes the following observation on the use of fir:—"That which comes from Bergen, Swinsund, Mott, Longland, Dranton, (called Dram,) being long, straight, and clear, of a yellow and more cedary colour, is esteemed much before the white for flooring and wainscot; for masts, those of Prussia, which we call spruce, and Norway, especially from Gottenburgh, and about Riga, are the best."

The torulus, as Vitruvius terms it, and heart of deal kept dry, rejecting the alburnum or white, is everlasting;

nor is there any wood which so well agrees with the glue, or which is so easy to be wrought. It is also excellent for beams, and other timber work in houses, being both high and exceedingly strong, and therefore of very great use for bars and bolts of doors, as well as for doors themselves; and, for the beams of coaches, a board of an inch and a half thick will carry the body of a heavy coach with great ease, by reason of a natural spring which is not easily injured. It was formerly used for carts and other carriages, and also for the piles to build upon in boggy grounds. Most of Venice and Amsterdam is built upon them. For scaffolding also, there is none comparable to it. Under the head of fir may be classed *cedar*, a wood of great durability, but too expensive to be used in Britain.

General Observations respecting Timber.

Evelyn makes the following observations upon timber; some of which are well worthy of attention:—

General observations.

"Lay up your timber very dry, in an airy place, yet out of the wind or sun, and not standing upright, but lying along, one piece upon another, interposing some short blocks between them, to preserve them from a certain mouldiness which they usually contract while they sweat, and which frequently produces a kind of fungus, especially if there be any sappy parts remaining.

"Some there are yet, who keep their timber as moist as they can by submerging it in water, where they let it imbibe to hinder the cleaving; and this is good in fir, both for the better stripping and seasoning, yea, and not only in fir, but other timber. Lay, therefore, your boards a fortnight in the water, (if running the better, as at some mill pond head,) and then setting them upright in the sun and wind, so as it may freely pass through them, (especially during the heats of summer, which is the time of finishing buildings,) turn them daily, and thus treated, even newly sawn boards will floor far better than a many years dry seasoning, as they call it. But, to prevent all possible accidents, when you lay your floors, let the joints be shot, fitted, and tacked down only for the first year, nailing them for good and all the next; and by this means they will lie staunch, close, and without shrinking in the least, as if they were all one piece. And upon this occasion, I am to add an observation which may prove of no small use to builders; that if one take up deal boards that may have lain in the floor an hundred years, and shoot them again, they will certainly shrink (*toties quoties*), without the former method. Amongst wheel-wrights, the water seasoning is of especial regard; and in such esteem amongst some, that I am assured, the Venetians, for their provision in the arsenal, lay their oak some years in water before they employ it. Indeed, the Turks not only fell at all times of the year, without any regard to the season, but employ their timber green and unseasoned; so that, though they have excellent oak, it decays in a short time by this only neglect.

"Elm felled ever so green, for sudden use, if plunged four or five days in water, (especially salt water,) obtains an admirable seasoning, and may immediately be used. I the oftener insist on this water seasoning, not only as a remedy against the worm, but for its efficacy against warping and distortions of timber, whether used within or exposed to the air. Some, again, commend burying in the earth, others in wheat; and there be seasonings of the fire, as for the scorching and hardening of piles, which are to stand either in the water or in the earth.[*]

"For that to most timber it contributes much to its duration. Thus, do all the elements contribute to the art of seasoning. . . . .

"And yet even the greenest timber is sometimes desirable for such as carve and turn, but it chokes the teeth of our saws; and for doors, windows, floors, and other close works, it is altogether to be rejected, especially where walnut trees is the material, which will be sure to shrink. Therefore, it is best to choose such as is of two or three years seasoning, and that is neither moist nor over dry;—the mean is best. Sir Hugh Plat informs us, that the Venetians use to burn and scorch their timber in a flaming fire, continually turning it round with an engine, till they have gotten upon it an hard black coaly crust; and the secret carries with it great probability, for the wood is brought by it to such a hardness and dryness, that neither earth nor water can penetrate it; I myself remembering to have seen charcoal dug out of the ground amongst the ruins of ancient buildings, which had in all probability lain covered with earth above fifteen hundred years.

"Timber which is cleft is nothing so obnoxious to reft and cleave as what is hewn; nor that which is squared as what is round; and therefore, where use is to be made of huge and massy columns, let them be bored through from end to end. It is an excellent preservative from splitting, and not unphilosophical; though, to cure the accident, painters putty is recommended; also, the rubbing them over with a wax-cloth is good; or before it be converted, the smearing the timber over with cow dung, which prevents the effects both of sun and air upon it, if, of necessity, it must lie exposed. But, besides the former remedies, I find this for the closing of the chops and clefts of green timber, to anoint and supple it with the fat of powdered beef broth, with which it must be well soaked, and the chasms filled with sponges dipt into it. This to be twice done over.

"Some carpenters make use of grease and saw-dust mingled; but the first is so good a way," says my author, "that I have seen wind shock timber so exquisitely closed, as not to be discerned where the defects were. This must be used when the timber is green.

"We spake before of squaring; and I would now recommend the quartering of such trees, as will allow useful and competent scantlings, to be of much more durableness and effect for strength, than where (as custom is, and for want of observation) whole beams and timbers are applied in ships or houses, with slab and all about them, upon false suppositions of strength beyond these quarters. For there is in all trees an evident interstice or separation between the heart and the rest of the body, which renders it much more obnoxious to decay and miscarry, than when they are treated and converted as I have described it; and it would likewise save a world of materials in the building of great ships, where so much excellent timber is hewed away to spoil, were it more in practice. Finally,

"I must not omit to take notice of the coating of timber in work used by the Hollanders, for the preservation of their gates, portcullises, draw-bridges, sluices, and other huge beams and contignations of timber, exposed to the sun and perpetual injuries of the weather, by a certain mixture of pitch and tar, upon which they strew small pieces of cockle and other shells, beaten almost to powder, and mingled with sea-sand, or the scales of iron, beaten small and sifted, which incrusts, and arms it, after an incredible manner, against all these assaults and foreign invaders; but if this should be deemed more obnoxious to firing, I have heard that a wash made of alum has wonderfully protected it against the assault even of that devouring element; and that so a wooden tower or fort at the Piræum, the port of Athens, was defended by Archelaus, a commander of Mithridates, against the great Sylla. But you have several compositions for this purpose, in that incomparable Treatise of Naval architecture, written in Low Dutch by N. Witsen, Part I. chap. vi. The book is in folio, and he that should well translate it into our language (which I much wonder has not yet been done) would deserve well of the public.

---

[*] When wood is charred, it becomes uncorruptible; for which reason, when we wish to preserve piles from decay, they should be charred on their outside. Oak posts, used in inclosures, always decay about two inches above and below the surface. Charring that part would probably add several years to the duration of the wood.

"Timber that you have occasion to lay in mortar, or which is in any part contiguous to lime, as doors, window-cases, groundsels, and the extremities of beams, &c. have sometimes been capped with molten pitch, as a marvellous preserver of it from the burning and destructive effects of the lime; but it has since been found rather to heat and decay them, by hindering the transudation which those parts require; better supplied with loam, or strewings of brick-dust, or pieces of boards; some leave a small hole for the air. But though lime be so destructive whilst timber lies thus dry, it seems they mingle it with hair, to keep the worm out of ships, which they sheath for southern voyages, though it is held much to retard their course. Wherefore, the Portuguese scorch them with fire, which often proves very dangerous; and, indeed, their timber being harder, is not so easily penetrable.

"For all uses, that timber is esteemed the best, which is the most ponderous, and which, lying long, makes deepest impression in the earth, or in the water, being floated; also, what is without knots, yet firm, and free from sap, which is that fatty, whiter, and softer part, called by the ancients alburnum, which you are diligently to hew away.

"My Lord Bacon, Exper. 658, recommends for trial, of a sound or knotty piece of timber, to cause one to speak at one of the extremes to his companion, listening at the other; for if it be knotty, the sound, says he, will come abrupt.
